The heat of the sun is supposed to be supplied by myriads of meteoric bodies in the vast regions of space.

The Southern Negro's "Jack."

One of the first questions asked by County Physician Wilder when the body of Dallas Stowe, the negro, was found hanging by a grapevine in the woods near town was: "Where's his 'jack?'" At this question the negro audience fell back as if getting away from a bomb that was about to explode. "What do you mean by his jack?" asked one of the white men present, "and why this commotion?" "Wait, and I will show you," said the doctor. He then felt in the pockets of the dead negro and brought out a tin box. He opened it, and it was found to contain a snake's head, a scorpion, a piece of iron, a rusty key, a bunch of "witch's yarn" and an ounce of salt. "This," said the doctor, "is the jack. Eight out of ten negroes carry them. With it they 'conjure' their enemies, throw a spell over them, and the average negro holds the jack in mortal dread. To show you their fear of it, just offer any negro here a dollar to put this box in his pocket." The offer was made, but no one would touch it. Dr. Wilder brought the box to the city and tried the darkies on it, but not one of them could be induced to touch it. The doctor hung this jack in his back yard, and says that his turkeys, chickens and woodpile are safe for this winter.—Charlotte (S. C.) News.

Be Wise and Richer.

Men are prone to make mistakes. This is notably true of many owners of mines who are unable to develop the same or to operate them on a profitable scale. Again and again have we observed poor men, wholly unable to operate their mines successfully, defeat themselves and the prosperity of the community by demanding an exorbitant price for a prospect. This should not be. We advise poor men to sell their properties at a moderate figure. It is wise to do so. It is far better than to demand two or three fortunes, and, by so doing, reap nothing but poverty. Capital can only develop and successfully operate big mining enterprises. It is willing to take chances. It can afford to do so, but the poor man cannot. To him the possession of a few thousand dollars is far better than the mere hope of securing many thousands. Therefore we repeat: Be wise and richer by selling your prospects at moderate prices. Push development work on them, stand by the progressive citizens who are trying to bring capital to the county, welcome the intending investor and be willing to share chances with him.—Pumas National Bulletin.

ONE of the most important questions of the day is, How far is it commercially possible to transmit water power electrically? Professors E. J. Houston and A. E. Kennelly have just made a compilation of facts and figures that serve to define very clearly the present status of this momentous issue, and estimate the distance to which Niagara water power can be economically transmitted by electricity. Although water power has not yet been made available at a greater distance than 25 miles, it has been generally considered that it could be distributed commercially at a radius of 50 miles. Messrs. Houston and Kennelly show that if reliable machinery can be bought cheaply enough, and the conductors can be safely operated at sufficiently high pressure, there is nothing to hinder the Falls of Niagara from stopping steam engines in New Orleans, La., by underselling their power.

THERE are now more than 8000 steam engines used for transportation service on highways in Great Britain. The fact was stated by Lieutenant Colonel Templer at the Royal United Service Institution some days ago, in a lecture advocating the use of steam transport for army purposes. He said that extensive experiments had shown that a train of wagons can, on the best roads make but 15 to 20 miles a day, while a traction engine can transport the same train 60 to 70 miles a day, and at less cost. Horses sooner or later give out, but the engine can keep right on, day after day, under all circumstances. The 8000 engines mentioned are, of course, used for a great variety of work, mainly about farms, beside simple transport.

A FRENCH ELECTRICIAN, M. Trouve, catches fish by sinking in the water a net with an incandescent lamp attached. The curious fish collect around the light, when a pneumatic tire around the edge of the net is silently inflated and rises to the surface, entrapping them without frightening them, and hence without destroying the spawn—a great drawback to ordinary net fishing.

THE cable informs us that Dr. Pean has presented to the Academy of Medicine at Paris a man 41 years old, whose voice, destroyed by a surgical operation, had been restored by Dr. Kraus, who made an artificial larynx for him. Insertion of the instrument is painless and easy. The larynx consists of a spinal silver tube covered with rubber.

Scientific Progress.

The Roar of Sun Spots.

Nothing has been heard lately of Mr. Edison's attempt to make the roar of sun spots audible by means of an electro-magnetic device connecting the earth currents with a telephone, says the New York Sun. The idea was that the impulses believed to be transmitted from the sun to the earth when great spots are forming on the solar surface might be translated into sound waves, thus, in a sense, enabling us to listen to the voice of the god of day when his temper is disturbed.

Recently an experiment of similar nature has been tried in England by W. H. Preece, and apparently with success. During the magnetic storm of March, which seemed to be connected with disturbances in the sun, telephones were inserted in some of the principal telegraph circuits, and they gave out various sounds. Sometimes the noise was like the twanging of musical strings or wires; then again it resembled whistling. Some observers hear reverberations in the telephone like the rumbling of heavy carts. Occasionally high-pitched notes and screeches were emitted, followed by low musical sounds like the laps of waves upon a beach.

While these strange noises were given forth from telephones attached to telegraph lines—one was the Liverpool-Hamburg wire—auroral lights, white, green and rose-colored, were seen in various places playing up and down the sky, and the earth appeared to be tingling with electric currents.

Evidently there is still a great opportunity for discovery concerning the origin and nature of such magnetic storms and their relation, if any, to the sun. So far, speculation has held the field in this direction, but a few facts are beginning to emerge, and any day a brilliant discovery may illuminate the whole mystery with a flood of light. Then, perhaps, we shall know whether it was the earth or the sun that made Mr. Preece's telephones sing and whistle and shriek, while the heavens shimmered with light that was not of the stars.

The Breathing-like Movements of the Earth's Surface.

Prof. John Milne makes it clear that the earth is breathing, and that the tall buildings upon its surface are being continually moved to and fro, like the masts of a ship upon the ocean. Although few countries are seriously troubled by earthquakes, important earth movements are occurring at all times and in all lands that have an appreciable effect on the surface configuration. These movements are now being studied by physicists. It is stated that in both Germany and Japan a tide-like movement of the earth is often distinctly apparent, the ground being gently tilted every 24 hours (more at night than by day), and hullings and chimneys are slightly inclined like stalks of corn in a steady breeze. So far as Japan is concerned, this phenomenon is attributed to the opening and shutting of the crumpled strata forming a range of mountains. The various movements of the panting earth have been classified, and among them are the microseismic or tremor storms, which are defined as long, flat waves like those of an ocean swell, and the heaving effect produced in certain districts by changes of atmospheric pressure. It is now found, too, that while the waves from distant earthquakes may be appreciable to the senses for only a few hundred miles, their vibrations may extend around the world.

The New Metal.

The newcomer, "silvinit," is an alloy composed chiefly of aluminum, and although it has been introduced with a flourish of trumpets, its practical status has not yet been determined. It has great lightness,

silvery luster, malleability and ductility, and, although comparatively soft, is tough and strong. In decorative work it may be used either in its natural color, which is not easily tarnished, or painted with oil colors, which it "takes" well. The manufacturers also claim that it enamels well, but if so, the enamel material applied must be fusible at an exceptionally low temperature, as the metal itself softens and fuses very readily. The suggestion that it would be a good substitute for corrugated iron for roofing is ill-advised. In the event of a fire, a silvinit roof would collapse very quickly, and thus cause a more complete wreck than would result if iron were in use. Sulphuretted hydrogen does not tarnish the metal, even after prolonged exposure; ammonia, on the other hand, distinctly affects its surface, while caustic alkalis and dilute mineral acids rapidly dissolve it. Vegetable acids, such as acetic, do not seem to produce any impression on the metal, but whether prolonged action, aided by alternate wetting and drying by exposure to air, will cause erosion, time alone can prove. There is undoubtedly a large field open for this valuable metal, but that it will really supersede any of the other metals in common use is not likely.

The Highest Windmill Tower in the World.

The town of St. James, L. I., can boast of having the highest and strongest windmill in the world. The proprietor of the land on which it has been erected tried for years to construct a well on the elevated land near his house, but without success. The spring from which the windmill pumps is on the beach at the head of a distant bay. The contiguous land rises so rapidly, and the trees are so high, that it was necessary to raise the windmill 150 feet, so that the bottom of the windwheel would be above all obstructions within 1000 feet of it. The scale on which the mill is erected can be seen from the fact that there are 20 barrels of concrete in the foundation piers, besides 40 barrels of cement, 20,000 bricks, 42,000 feet Georgia pine, and more than six tons of bolts and washers and iron plates. It is 22½ feet in diameter and 190 feet above high water. There are 6000 feet of pipe between the windmill pump and the reservoir, which contains about 65,000 gallons. The windwheel has frequently filled it in two days. The maximum height to which the water is forced by this mill is 223 feet, before reaching which it has to pass a long line of pipe. There is no difficulty, however, in making a plant to throw the water much higher than this. It is merely a question of the pump, pipe and fittings being able to withstand the pressure and the windmill being large enough to give power sufficient to do the work. Pumps are made strong enough to raise water 2000 feet, if necessary. The only question to be carefully considered is that of the tower, for it must be made to withstand the roughest weather likely to be met with in those latitudes.

Science and Americans.

Science is supreme in American production, and the Americans have outrun us all in its application. They were the first to utilize electricity, not merely in the development of telegraphy and the kindred arts, but as a powerful ally in manufacture. In the welding of metals, for instance, it now plays an important part. It has reduced the price of aluminum from £2 to 2s. a pound, and the metal has now in consequence passed into common use; it enters into the fabric of the bicycle; it is made into shoes for the horses of Russian cavalry; it is embodied in the ignifugal figure which crowns the Shaftesbury Memorial.

In iron and steel, the use of highly developed machinery, which is no more than the application of science, has revolutionized

production. The new drop-hammer has brought down the price of American plows to less than £1, and in the making of all sorts of agricultural implements it is calculated that 600 men can now produce as much as 2145 men could a few years ago. Where a single workman could make three dozen pairs of sleeve links in a day, a boy can now make nine thousand.

The manufacture of pins still holds its own as an "object lesson;" but whereas Adam Smith notes with astonishment and admiration ten men turning out 48,000 pins a day, the modern American manufacturer finds no difficulty in supplying 7,500,000 in the same time, as the result of the labor of five pairs of hands. Compare this with the state of things at the time of the War of Independence, when imported pins sold for 7s. 6d. a dozen, and when, to encourage home industry, the Government offered £50 for the best 25 dozen of pins made in America equal to those imported from England.—The Edinburgh Review.

PROF. LAWSON TAIT says there are certain orchids that secure the fertilization of their stigmas by making bees drunk. In no other way could they get these insects to cut up the necessary antics to carry the pollen to the proper place. Every such flower is a veritable liquor saloon, licensed by nature. The beverage supplied is distinctly alcoholic.

Metallurgy and Ores.

SELBY

Mechanical Progress.

How Matches Are Made.

There are many persons now living who can remember when the common method of obtaining fire for domestic and other purposes was by means of flint and steel; the sparks which fell from striking the two together, falling upon a piece of punk, or dried, decayed wood, or carbonized linen or cotton goods, when fanned into a flame, producing the necessary heat with which to start a fire. This primitive method was in general use until the early part of the present century, when the first successful attempt was made to produce fire for ordinary purposes by means of chemical agency, but it was not until about 1827 that the first friction matches were considered of practical use. In 1833 they became an item of commercial importance throughout Europe, and were soon after introduced extensively into this country.

The expansion of the business since that time is shown by the annual statement of the Diamond Match Company at its meeting in Chicago not long since. President Barber's annual statement showed that the business for the year 1893 had made a net profit of \$1,359,577.15, as against \$1,050,000 in 1892—a remarkable showing for a year of such great business depression. This enormous sum represented 15 per cent on the invested capital.

When the internal revenue law was in force in the United States, the tax at one cent a box, in 1881, amounted to \$3,172,258. Since then the business has steadily increased. In Great Britain the yearly output is valued at about \$8,000,000, or upward of 300,000,000 matches daily. In France the Government has exclusive right to manufacture matches, for which privilege it pays annually 16,000,000 francs, or \$3,200,000, and has the business concentrated in about a dozen large establishments. Norway and Sweden have been among the largest match-producing countries of the world, their exports amounting to about 20,000,000 pounds of matches per annum. In Germany there are now upward of 200 factories, producing about 70,000,000,000 matches yearly. In Austria there are more than 150 factories, the output of which does not fall much below each of the other countries named.

It is difficult to ascertain the average number of matches daily used by each person, but in Europe the highest authorities place it from six to ten. It is probable that the proportion is still greater in the United States.

The wood used in the manufacture of matches is principally white pine, poplar, aspen and yellow pine. In the United States white pine is used almost exclusively. It burns freely, steadily, slowly, constantly and with a good volume of flame. The wood is soft, straight grained, easily worked, and its light weight is of no small consequence in the matter of transportation charges, which are usually high on combustible articles.

For the best grade of matches the choicest quality of cork pine is used, a variety of white pine, the trees being large and well matured. The Diamond Match Company about 12 years ago secured hundreds of millions of feet of choice standing cork pine timber on the waters of the Ontonagon river in the upper peninsula of Michigan. This company now cuts annually upward of 30,000,000 feet of this timber, but this is by no means all that is used in the manufacture of matches in this country. Millions of feet more of choice white pine timber are bought every year and made into matches by a number of factories under control of this corporation.

In Sweden the method of manufacture is as follows: The timber is cut into blocks about 15 inches long and placed in a turning lathe. With each revolution a slice or veneer

is peeled off the thickness required for the match sticks, while at the same time eight small knives cut the slice into seven pieces, like ribbons, and of the length required for the sticks. These ribbons are then broken into lengths of six to seven feet, knotty and defective pieces are removed, and the ribbons are then fed through a machine which cuts them into pieces like a straw-cutter, these then passing through an automatically arranged machine with cutters, which slices off as many pieces, the thickness required for a match, as there are cutters. One machine will turn out from 5,000,000 to 10,000,000 match splints in a day.

In this country choice, clear two, three and four-inch planks are used, also pieces from the ends of planks and timbers, edgings and other suitable parts of the log not utilized. These are cut the required length and sliced or split by machinery adapted for the purpose. After passing through these machines, the match splints are dried in heated revolving drums, during which process the loose splinters clinging to the splints are separated. They are then placed in a sieve and sifted, an operation which finally places the sticks in parallel order so that they can be conveniently banded, after which they are ready for the dipping operation.

The head of each stick, to be thoroughly dipped or covered, must be separated from the others, that no danger shall ensue from ignition, as would be done if they came in contact with the inflammable material used in the coating. The sticks are separated by machinery and placed each by itself in a dipping frame which is fitted in a movable lathe, and a number of these lathes are placed in a machine. One person can arrange with one of the machines nearly 1,500,000 splints in a day. The splints are then heated so as to more readily absorb paraffine, which is confined in its molten state in shallow pans.

The first dipping covers the head of the match sticks with the paraffine preparation; by the second operation it is covered with the igniting composition, different devices being used for this purpose. A competent person will dip about 8,000,000 matches a day. After the last dipping the frames containing the matches are placed in a heated room, that the igniting composition may be dried. They are then removed from this room and packed in boxes ready for shipment.—Chicago Journal of Commerce.

Glass Impervious to Heat.

Glass that resists so high a temperature as to be practically fireproof was reported from Germany a few months ago; and now, in the same country, it is said, glass is made which will transmit light freely, but not heat. For example, a plate of this material, four-tenths of an inch thick, containing 2.8 per cent of iron in the form described as "ferrous chloride," allowed only 4.06 per cent of radiant heat to pass through it, while another plate of equal thickness, and containing quite as much iron as "ferric chloride," permitted 11.2 per cent to pass. The chemical distinction is exceedingly small, but the effect is very marked. Uslog oxide instead of chloride, and again having it in a ferrous condition, one per cent produced a glass having a very faint blue tinge, but even more impervious to heat than the other sample. A layer .332 inch in thickness allowed only 0.4 per cent of the heat from a bat's-wing gas flame to pass through, 0.72 of that from an argand burner and 0.73 of the heat from a lime light; but it would transmit 12 per cent of heat from sunlight. Ordinary window glass, though, lets 86 per cent through. The chief use to which the discovery will be devoted at first probably will be the manufacture of lamp and gas shades, and possibly decorative work in connection with electric lighting.

PROF. JAMES MCLEAN of Chicago is trying to revolutionize traction by using com-

pressed air on engines in the place of steam. This would greatly change the shape of locomotives. He would put his air-tank where the cab now is, do away with the boiler and tender, and employ a rotary device instead of a reciprocating piston, in order to apply his power to the driving wheels. He doesn't say where he would put his engineer.

New Metal Cutting Saw.

A new metal-cutting saw has been devised by W. Hartman of Fulda, Germany. The cutting edges of this saw are inclined alternately in opposite directions, all the leading points and all the succeeding points of the cutting edges being at an equal height, and the sides of the blade may be ground behind the cutting points to the surface of a hollow cylinder. The leading cutting points may be deeper than the succeeding points of the same cutting edge, so that each single tooth is set, with regard to its cutting edge, after the manner of a turning or planing tool.

To make edge tools that are brittle and hard hold an edge, put them in boiling fat for two hours; then take them out. Treated in this way they will retain their hardness without being brittle. Another simple remedy for tools that are too hard is to light a piece of paper and run it across the edge after grinding. This will draw the temper just right.—The Industrial American.

THE statement is made that the band re-saw is fast displacing the circular re-saw for re-sawing lumber, on account of the thinner kerfs made by the band re-saw and the simplicity of the machine itself.

Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Electric Progress.

"Unknown" Causes of Fires.

H. C. Cushing, Jr., says: Any fire which takes place in any city of considerable size is recorded as to location, loss, amount of insurance carried, and the cause, or supposed cause of the fire. In the city of Boston there were, during the year 1893, 1233 fires, with a loss of \$5,024,765.04. Twenty per cent of all these fires are from unknown causes. When these unknown causes cost property owners more than \$1,004,955, it is about time that some investigations were made beyond attributing these causes to spontaneous combustion, incandescent or arc light wires, or to any other wires which enter a building. When an inspector cannot satisfy himself that it was from stoves, careless use of kerosene or matches, it is a very easy thing to lay it to spontaneous combustion or the unfortunate electric light wires.

The person attributing fires to the electric light wires being crossed with some trolley or other high potential wire outside is probably not aware that every wire entering a building is thoroughly protected at its entrance by a fusible metal which will blow out at any overcharge, thus deadening every wire in the building; and, moreover, there would have to be a decided ground within the building, which is nowadays a very rare occurrence, as the writer's investigations have proved that out of 25 prominent buildings in the city of Boston the insulation resistance to ground proved to average over 2,000,000 ohms. But when I say that the electric light and power wiring should not receive the blame as often as it does, I do not mean to take the responsibility off of electricity, for it is through this agent that I have reason to suspect the origin of many of the "unknown" causes, so-called, in fire reports.

When electricity is allowed to roam at large and in vast quantities all along our water and gas pipes and through the ground upon which the city is built, in order to get back to the sources from which it was generated, which are the street railway power stations, it is this state of affairs which is creating a trouble, the extent and seriousness of which is only known to those few who have made it a study. These street railway power stations, operating the overhead trolley system, are constantly generating thousands of horse power of electricity, sending it out by overhead trolley and feed wires to the cars which it operates, and returns it to the station by means of the water and gas pipes which lie in its course. For this reason there is a tremendous electrolytic action going on all the time. When I speak of this trouble from electrolysis I do not mean that Boston and Cambridge are the only cities affected, but every city in the United States operating a trolley system with ground returns. The writer has samples of gas and water pipe completely eaten through by electrolytic action in three months after having been placed in the ground near street railway returns. This effect has been going on and will continue to go on as long as there is a grounded wire in electric street railway construction.

Wherever this returning current flows in any quantity along a pipe there is bound to be a large fall of potential, varying in different pipes as their carrying capacity increases or diminishes.

In the cellars and basements of many houses I have found quite a large difference of electrical pressure between two pipes entering within one foot of each other, and in one instance it was a very easy matter to take a piece of hoop iron and draw an electric arc sufficient to ignite a piece of waste held near it, and by connecting these pipes together with a piece of No. 18 copper wire, the current flowing through it was sufficient to heat it so that it was impossible to lay

one's hand upon it. In the basement of another building, not 200 yards from where the writer sits, I find a man using 25 amperes at 8 volts pressure, or electricity enough to run small motors and incandescent lamps, as well as the electric bells in the entire building, by simply twisting his wires around two different water pipes which enter the building.

Some time ago my attention was called to two pipes which were so close together that the vibration of an elevator engine caused them to knock together just sufficient to create an arc every time a contact was made and broken. This had been going on so long that it had almost completely eaten through the gas pipe, and it is perfectly evident what would have taken place had this been allowed to go on unobserved. The gas would have been ignited, as soon as the first small hole appeared, by the electric spark, and disastrous results would have undoubtedly followed.

The difference of electrical pressure upon water and gas pipes is now so well known that in a number of cases in the cities of Boston and Cambridge the ordinary electric bell battery is entirely discarded, and the wires from the bells connected directly to the water pipes, the latter furnishing an inexhaustible supply of electricity at the proper pressure to run any number of bells or gas-lighting apparatus, and also to do any quantity of mischief. I can see no reason why fires should not be attributed to this cause, when it can be proved that such a difference of electrical pressure really does exist between any two pipes entering a building in the vicinity of the trolley system of street railways.

There is only one way of eliminating this rapidly increasing danger, and that is by compelling the electric street railway companies to insulate, from the ground, their entire electrical circuit, and just as soon as a suit for damages is brought by the water and gas companies for a complete system of pipes destroyed by electrolysis, the railway companies will begin to remedy the evil, which they are more fully aware of than any one else.

Electricity in Plants and Fruits.

There is no doubt, says *Le Genie Civil*, that nature makes use of an as yet little known but important property of electricity in its different forms for making plants grow, flowers bloom and fruits ripen. It is a secret that it will disclose to us one of these days. Some quite curious experiments in electric culture have already been made in different places, and results have been obtained that appear to be satisfactory, but they have not yet the definiteness and permanence that would permit of profitably converting our fields and kitchen gardens into electric batteries.

It has been ascertained, however, that fruits are in a continual electric state. Upon puncturing them at the top and bottom and closing the circuit, it has been possible, by means of a multiplier, to study the variations of such electric state. The ascending sap of trees and the cortical sap, which have not, as well known, the same chemical composition, react upon each other and afford marked electric phenomena. From the pith to the cambium the layers are less and less positive, and from the cambium to the epidermis they are more and more so.

What will be the result of future studies upon this subject undertaken with commendable patience? We can only make a surmise. In the intensive hothouses called forcing houses fruits are already obtained at all seasons, and the electric light is used for giving the forced plants the impression of the dawn and of the high and setting sun. They are very sensitive thereto.

Perhaps upon combining this external action with the passage of an appropriate current into a soil charged with chemical products that it would decompose, we might

succeed in producing astonishing fruits and flowers in hothouses, and, with the wand, make forests grow in bare gardens. There is nothing improbable in such magic, seeing that electricity, according to experiments already made, plays a role as mysterious as preponderant in vegetation.

A NEW application of electricity to manufacturing purposes is reported from Germany in connection with the use of metal plates for pressing and finishing woollen goods. Such plates, which require to be heated, have hitherto usually been warmed either in an oven or by means of steam, but both of these processes are troublesome, and involve loss of time, besides leading to uncertainty as to the temperature obtained. It is now proposed to heat the plates by electricity.

AN electrical experiment of great interest was recently conducted by Prof. Julius Friedenwald at the Baltimore College of Physicians and Surgeons. By means of a flexible rubber tube a diminutive electric light was introduced into the stomach of a patient and, the lights in the room being lowered, over 200 persons viewed the workings of the patient's organs through the transparency which the light created in the abdominal wall.

A COMPANY has been formed to utilize the water power in Big Cottonwood canyon, fourteen miles from Salt Lake City, and convey the energy to the latter point as electricity. For two-thirds of the year, it is said, 3000-horse power will be available, and for the rest only 2500.

Practical Information.

To Prevent Iron from Rusting.

Following is the substance of an essay recently read before the Paris Societe d'Encouragement by Octave de Rochefort-Lucay, on the Bertrand process for coating with magnetic oxide and enameling iron and iron carburets, and on a new process of tinning for cast iron. Barff and Bower were the first, practically, to coat iron, steel and cast iron with magnetic oxide so as to form, at the cost of the metal itself, the protective layer that is obtained usually from paint or enameling, with a thin coating of the metal that is not oxidizable. The Bertrand processes are more simple than those of Bower and Barff and are based on a new discovery in chemistry, which may be stated thus: If a thin adherent film of another metal is formed on the wrought iron or on the cast iron, and this iron or cast iron, heated to 1000 degrees, is exposed to a current of oxidizing gas, the oxygen penetrates through the film and oxidizes the iron or the cast iron, and magnetic oxide is the result. The formation of magnetic oxide thus obtained continues indefinitely, and the thickness of the coating of oxide increases according to the period of exposure to the oxidizing current, providing the temperature remains at about 1000 degrees. The film of metal deposited in the first instance disappears in some obscure way, forming oxides which mingle with the magnetic oxide or volatilize, according to the nature of the metal of which they are composed. M. Bertrand had to find the best method for depositing it on the article to be coated, and he has found that bronze—a mixture of copper and tin—gives every satisfaction. For depositing this bronze on the wrought iron and cast iron, M. Bertrand uses electricity or wet baths and sulphophenolic acid. The following is the method adopted in the Bertrand manufactory for an oxidation: The article is cleansed (the cleansing is not indispensable) and then dipped a few moments in a bath containing a solution of sulphophenate of copper and tin. The coating of bronze being formed, the article is immediately washed with cold water and dried with saw-

dust. The article dried is put into a furnace. Oxide forms, and at the end of 15 to 30 minutes, according to the articles, the article is taken out, sufficiently oxidized. The coating produced varies from 1 to 10 mm. to 1-5 mm. M. Bertrand uses electricity to ascertain if the coating is of sufficient and uniform thickness, and in so doing he makes use of bells. If, in putting the two wires in contact with the oxidized articles, the bells ring, the current passes, the oxidation is insufficient; if it remains silent, the oxide formed is of sufficient practical thickness, because it prevents the electric current from passing.

Process of tinning cast iron: M. Bertrand has used sulphophenolic acid to obtain tinning on iron. He dissolves salts of theine in a mixture of water and sulphophenolic acid at the rate of one per cent of theine salt and five per cent of sulphophenolic acid. In this mixture the article, which is previously cleaned, is dipped, and it is at once covered with an adherent coating of tin, and afterward, by means of rotating brushes in wire and cloth, the coating of tin is polished and a result is obtained that is both effective and cheap.

Process for enameling: There are not more than two processes for enameling cast iron. In the first, called hot, the iron, heated to a vivid red, is powdered with a flux powder, boro-silicate of lead, distributed with a sieve, then it is heated, and when the flux fuses, it is powdered afresh with glass, more soluble, forming the glaze of the enamel. This process is dangerous to the operator and even impossible for large articles, nor does it allow decorations. The second process consists of dressing the cast iron by three distinct and successive operations in the furnaces with a kind of pottery. In the Bertrand enameling the article is first coated with magnetic oxide, then dipped in boro-silicates of lead colored by metallic oxides, to which is added a pipe clay in order to give more body. The article thus covered cold, by dipping or with brushes, is put into the furnace; the enamel adheres and vitrifies at the usual furnace temperature used by enamellers. By putting a coating of colored enamel with a brush on a first coat simply plain, it is possible to make any decorations desired, which may be burnt in at one operation for outdoor vases. These results, due to the first oxidation with magnetic oxide, are remarkable as much for the color as for the tenacity of the enamel and its resistance to rough usage.—Iron Industry Gazette.

Where Scrap Iron Goes.

Nothing goes to waste on a big railroad, and every scrap of iron and much second-hand material is valued at a fixed price and carried on the books as so much stock on hand. The system followed by the storekeeper's department of one railroad is a sample of many. The second-hand metals are gathered and placed in piles, regularly assorted. Then they are classified by the foreman and taken into stock by the storekeeper or assistant. There are regular schedules—one of material which can be used again, which is denominated "second-hand," and another of material which has to be melted before it can be used, which is known as "scrap." The classes are arranged something after the following order: Steel scrap, Nos. 1, 2, 3, 4, 5 and 6, at prices ranging from \$28 a ton down; wrought iron, Nos. 1, 2, 3 and 4; cast iron, Nos. 1, 2, 3 and 4. Even borings are taken into account, brass borings being credited at eight cents per pound, and brass scrap and copper at twelve. This material is shipped to division headquarters when a carload has accumulated. Here it is disposed of by the storekeeper on order of his chief, being shipped in carloads to big dealers in old metals in large cities. Much of it goes to Pittsburg, Cincinnati and such points. Orders for as high as 500,000 pounds of one kind of material are occasionally received from single firms. Most

of the second-hand material is used over again in the shops, but it is previously taken on the hooks at a fixed price by the store-keeper and is charged up to the account of the articles for which it is used. All usable No. 1 wrought iron is received and charged up at one and one-fourth cents a pound, and cast iron at one cent.

Warmth from Paper Clothing.

The successful inventor is not always the man whose ideas are new. He is often the one who puts an old idea to a new and important use, incidentally improving it in detail. It is proverbial that a single newspaper spread over a bed on a winter night will give warmth to persons sleeping therein; and it is common for guards on elevated railway trains, for teamsters and for other people much exposed to cold to stuff the same material inside their coats for the same purpose; and they secure the same result. J. C. McLaughlin therefore said to himself one day, "Why not have a special paper for such uses?" And his answer to himself is a patent, taken out two or three months ago, for what he calls "fibre chamolins." This is made from the best quality of chemical wood pulp, preferably spruce, treated by the Mitscherlich process. His product is paler than unbleached muslin, as thick as the kid from which shoes are made, almost or quite as pliable, tough enough to hold stitching, light in weight and very warm. This material is specially adapted for interlining of waistcoats, overcoats, jackets and skirts; although with a detachable chintz cover it may be used for bedcoverings and can also be worked up into garments not intended to go into the washtub. It is better not to have it exposed directly to wear, weather or water; but suitably covered, it promises to become serviceable as a substitute for more costly goods. Mr. McLaughlin claims that it is sufficiently porous to allow exhalations from the body to escape, yet close enough in texture to exclude dust. Warmth with lightness will be its strong point.

Insurance and Gambling.

Certain forms of wagers are approved at the present day universally by statute law. The most familiar forms are fire and life insurance. It is perhaps of interest to note here that those forms of wager, now so common and so universally approved, came into popular use slowly, against a strong current of disapproval, upon the ground that they were immoral. As late as 1803, in the State of Pennsylvania, life insurance policies in which the assured had no interest were held to be void.

There is no form of contract which comes nearer to the essential features of a wager than fire insurance. What does a person buy for the premium which he pays? No certain return, only this: That in the remotely possible event that the building insured shall be burned, then the insurer agrees to make good the loss up to the amount of the policy. The amount of premium bears the same ratio to the sum guaranteed as the chance of burning does to the chance of not burning.

AN EFFICACIOUS REMEDY for obstinate cases of insomnia is to lie flat upon the back and inhale and exhale deep, long breaths; take 30 or 40 of them, then turn on one side—preferably the right—and sleep will come before you know it, unless you have the pernicious habit of taking your work to bed with you. The facility with which we can rest and recuperate from great fatigue, either mental or physical, depends largely upon our power of dismissing thought and encouraging a state of vacuity. It is a question of habit, but one which is in every one's power to acquire; and of so great value that it is worth more than a slight effort to win. — From "Sanitarian," in Demorest's Magazine for May.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

**Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.**

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Ochromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

It is proposed to turn a portion of the unfinished Panama canal to account. During the stormy weather the port of Colon is difficult of access. On the Panama side vessels lie at anchor in the bay, and cargoes have to be lightered to and from the city. It is now suggested to utilize portions of the abandoned canal for improved harbor facilities. For this purpose four miles on the Panama side, and about 14 miles on the Colon end, could be rendered available, securing safe harborage for vessels and enabling cargoes to be transferred from steamers to the cars of the Panama railway.

At Great Falls, Mont., the volume of water passing in the upper Missouri is about 4800 cubic feet a second, and at Fort Benton (twenty-five miles farther down stream) United States engineers report it at 4331; and now the question arises, what becomes of the rest? A helief is entertained that the water drains off through the sand and supplies the great artesian well basin of South Dakota.

A LARGE irrigation enterprise is about to be undertaken in Mexico. A contract has been signed for works consisting of a dam six miles above the junction of the San Juan and Rio Grande rivers, and some 100 miles of canals and laterals, which will, when completed, permit the irrigation of 500,000 acres of good cotton land.

INSTRUCTION BY MAIL

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhes Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior. In proximity to the mines mentioned.

CALIFORNIA.

Amador.

Dispatch: A company of experienced and wealthy mining men have taken hold of the Clinton Bar mining claim, on the Mokelumne river, a few miles from Aqueduct City, in which F. M. Cook of the Oneida is interested, and will commence work at once on an extensive scale. Mr. Chase will have the management.

The Kennedy mine is to be pushed down to a depth of 2000 feet, and arrangements are now being made for the work. The sinking will be done by contract, the contract to be given to some of the regular workmen at the mine.

THE MAYFLOWER.—*Record:* The Mayflower gold mine at Amador City extends from Ranceria creek to the north line of the Keystone mine, and includes the Bunker Hill, Mayflower and South Mayflower, the Little Amador and King mines, covering an area of nearly 5000 feet in length, with a width varying from 300 to 600 feet. Near the north end of the property is located the 40-stamp mill and hoisting works of the old Bunker Hill mine, in which region and on the adjoining Mayflower ground the most of the present development work is being done. Some 80 men are now employed, and 20 stamps are at work. It is expected that the additional 20 stamps of the mill will soon be at work crushing the output of this part of the property. The company is preparing to reopen the Johns shaft on the south side of the ridge near Amador City, on the Little Amador property. This shaft was originally sunk to the depth of 700 feet. When cleaned out and repaired, development work and further sinking will begin from that point. As soon as developments will warrant, a new 40-stamp mill with all modern improvements will also be erected.

Calaveras.

Echo: Angel's Camp has more idle men looking for work than any other town in the State, and a public mass meeting was held by the citizens of that burg last Sunday night to take steps to drive bad characters out of the town. The Viertong mine, composed of five claims, has been sold to a Montreal syndicate for \$150,000, and will be opened within 60 days. It will give employment to 500 men. A 100-stamp mill is to be erected and 40 concentrators will be used. The Excelsior mine on Albany Flat has also been sold, and negotiations are being made for the purchase of the Birney mine and an abandoned one on Carson creek.

TAKING PRECAUTIONS.—*Prospect:* The Utica Company evidently does not intend to be caught napping, and the rich treasure which is weekly turned out of the mills, and which is a tempting bait for desperadoes, is well guarded. Ten special deputy sheriffs have been sworn in to guard the property, and at night they patrol the grounds and buildings armed with ugly looking Winchester. Street lamps have also been placed at intervals over the grounds belonging to the company, so that at night every part of the premises is lighted, and it would be hard work for any underlenders to escape the detection of the watchful guards.

QUICK WORK AND GOOD RESULTS.—*Angels Echo:* Six weeks ago a little man, dressed in corduroy pants and working clothes, registered at Dolling's Hotel, as J. V. Brooks, of Louisville, Kentucky. Nobody in the town knew him, except Charley Tyrone, who received through him a letter of recommendation from E. K. Stevenot. The morning after Mr. Brooks' arrival he engaged a team and started for Chaparral Hill, near Albany Flat, to look at some mines, and some person in town spread the report that the little man was here in the interest of Angels. In fact it leaked out that he had among us the great little Prof. Brooks, the man who is known in the West as the identical individual who makes or kills the sale of mines.

The professor has banded his work with wonderful dexterity, made recent and hurried trips to San Francisco and Angels and with the following results: He has sold to a Montreal syndicate, with a large capital to back him, the Viertong mine, composed of five claims, for the sum of \$150,000. He has contracted with a Holland syndicate for the purchase of the Birney mine. He has sold for Fred Brunner the Excelsior mine on Albany Flat, and Carson creek will have an old abandoned mine opened and sold by the little man from Kentucky. Such a man as Prof. Brooks is the kind of an expert that Angels will always welcome with open arms.

We are informed that the Viertong mines will be opened within 60 days and will give employment to over 500 men.

Mono.

A STRIKE IN BONNE.—*Miner:* For the past month or so Bodie stock has been going up, and rumors have been heard to the effect that a strike had been made. Superintendent Kelly this week reports that he has five feet of high-grade ore in the north drift from west crosscut No. 1, 300-foot level.

Nevada.

THE MT. GEORGE.—*Herald:* The owners of the Mt. George mine, located out on Rush creek, are about to remodel the hoisting works and put in Pelton water wheels, so that the mine can be developed faster. Wm. May will do the work. The Mt. George has paid its owners about \$40,000, and the present owners confidently expect to make more than that out of it very soon. It is a mine which has paid from the grass roots down, and has never been prospected to any depth. Its late owner made

a living out of it for years by just scratching off the top, and the new company, comprising Frederick Zeitler, Dr. C. W. Jones, John F. Kidder and others, ought, with improved machinery and skilled miners, to make a lot of money out of it.

WILL RESUME.—Edwin Tilley is about to resume operations on the Midnight, located on Deer creek, just below Suspension bridge. The mine has lain idle for a couple of years.

A NEW MILL.—The Osborne Hill mine, below Grass Valley, is to have a new 20-stamp mill. Work has already begun on it.

STAUKE RICH OAR.—*Union:* Last week an unexpected strike of importance was made in the incline shaft being sunk on the Sunrise mine (Sebastopol) on Osborn Hill. The ledge is of good size, abounding mineral and gold in nearly every piece of ore examined, and is estimated by those who are good judges to be worth \$100 to \$150 a ton. A strike in the above locality means much, as failures there are few and far between. Machinery will soon be placed on the mine and a contract let to sink the shaft 100 feet.

Placer.

Colfax Sentinel: Mr. Roderick, of San Francisco, is about to erect a ten-stamp mill on the Zipp & Sleszenop mine, at Blue Canyon. This is not a new mine, as it has been worked for the past seven years, has a five-stamp mill already, and has paid. This will make three ten-stamp mills for eastern Placer within six months.

Plumas.

GOPHER HILL.—*National-Bulletin:* The company owning this mine has two large streams playing upon the gravel deposits—one 54-inch monitor and one 6-inch, under a pressure of 350 feet. The smaller one will throw a stream about 320 feet. The restraining works and settling reservoir below the mine do their work well. The matter carried over the dam in suspension is less than 1 per cent. All the rock and sand is effectively stored, none of it reaching Spanish creek. The sediment carried in suspension is an extremely fine, impalpable substance not calculated to do any injury to either lands or navigable streams. The company is acting in the utmost good faith; its method of working is eminently successful. They have a fine bed of gravel, and it is believed to contain much gold.

THE PRONAR.—This mine, at Grass Flat, is paying well. Thistle Shaft, below Gibsonville, employs between 50 and 60 men, and is meeting with the usual success. The Slate Creek mine, under the superintendency of Mr. Moyle, has been operating about ten days by means of the elevator process, which is handling the gravel with great rapidity. Several men are working at the Excelsior.

THE NORTH FORK.—The King mine, owned and operated by Fred Scott, is developing into a fine property. Last week the clean-up from the work of four picks in a little more than two days was 18½ ounces of gold, or about \$325. He owns nearly a mile of the Big Flat channel and is working at the lower end of the claim. Not much over 100 feet of the channel has yet been mined, but the yield has been very satisfactory thus far.

Riverside.

The Winchester *Recorder*, in speaking of the mining industry in Riverside county, says more attention is given to mines and mining than ever before. Many think that the sale of the Good Hope mine some months ago is the cause of its revival, others that the absence of other employment has led many to develop old prospects that proved to be richer than at first supposed; yet whatever the reason for this activity, the fact remains that the known mineral resources of the county are constantly increasing.

Work is steadily progressing on the mines around Winchester—the Snowbird, the Alice and others—and their owners have unbounded confidence that they will prove rich producers when developed.

San Bernardino.

The Holcomb Mountain Mining and Milling Company of Los Angeles has a capital stock of \$300,000. Their mines are located in San Bernardino county and are reported rich in placer gold. A carload of machinery was recently shipped.

Plant & Pierce, from San Bernardino, have bought the steam arrastras which were at Old Woman's Spring, and have moved them to a gold mine of theirs near the once famous Green Lead mine.

The Holcomb Valley Company started up their placer works about the 1st of April. The new machinery for amalgamation is working better than last fall, but is not yet as complete a success as could be desired. C. L. Metzger & Co., who have a large number of claims, will commence work in a few days.

The Riversiders have changed their superintendent once more on the Rose mine; Dr. Shugart holds the reins now. Some of the miners think it was time for a change, as they claim provisions were short during the winter.

The Morongo King Company are slowly putting up their ten-stamp mill. This week several carloads of pipe are being freighted in.

A half interest in the Surplus mine in Rattlesnake Canyon has been sold by Mat Morris to Metcalf Bros. The price is said to be \$5000, \$500 of which was paid down. They are running a horse arrastra on the ore from this claim.

Shasta.

A RICH STRIKE.—*Democrat:* R. G. Hart, of the Texas Consolidated Gold Mining Company, says that an immensely rich body of ore has been encountered in the Texas Consolidated in Old Diggins. The strike was made in the lower tunnel—No. 5—last week. The rock in the new discovery assays \$1100 per ton.

ARIZONA.

AT DOS CABEZAS.—*Tombstone Epitaph:* The Casey brothers of Dos Cabezas are in town. They are investigating the cyanide process as it is worked in Tombstone district, with a view to introducing it at their mine. They report a bright outlook for Dos Cabezas. The lessees of the Philadelphia mine are working their ore with good results. The ore continues to increase in richness, and ten stamps are dropping tight and day on the ore. The water supply is unlimited.

At the Silver Cave mine two Crawford mills are rapidly being placed in position to begin active operations.

At the Huntington mill, in Coopers canyon, the work of piping water from up the canyon is going on, and when completed a sufficient supply will have been developed to run the mill night and day.

Tombstone Prospector: Two carloads of leather in bond went over the N. M. & A. yesterday, bound for Joliet, Indiana, where it will be treated before shipment to England. There were 45,000 pounds in the shipment, valued at Gnyamas, where it was tanned, at 12 cents per pound.

George Fitts has received a piece of ore weighing 150 pounds from the Copper Glance mine at Camp Israel, in the Huachuca mountains. It represents a recent strike in the mine, the ore of which is valued at 300 ounces silver, \$15 gold and 47 per cent copper per ton. The camp is commonly called the Salvation Army camp, and is growing into a lively community.

Mr. Eltonhead, whose efforts with electricity and cyanide have met with such pronounced success in Tombstone, has just cleaned up a beautiful lot of amalgam from the plates which he has been using in his experiments. The most gratifying feature of the 20 pounds which he gathered was not in its weight, but in its fineness. It is 990 fine, showing conclusively that in precipitating the gold and silver by the electro process no foreign metal is gathered. The last test made by Mr. Eltonhead was with a 35 per cent manganese ore, from which he saved the remarkable proportion of 95 per cent of silver contained therein.

NEVADA.

Washoe District.

Regarding Con. Cal. and Virginia last week's letter says: On the 1650 level the south lateral drift which entered the ore body at a point 120 feet south from the winze and 14 feet below the sill floor has been extended during the week 7 feet in ore of high grade quality. This extension makes the total length of the drift 25 feet, in good quality ore. The drift has been further extended four feet in quartz and porphyry formation of low assay value.

The ore extracted during the week from this drift, together with some ore of a lower grade extracted from the vicinity of the winze, 52 feet down, amounted to 152 carloads, about 150 tons; the average assay value, per car samples, is \$88.91 per ton.

A west crosscut has been started from the north drift, 28 feet below the 1650 level and 14 feet below the ore cut in No. 2 south drift. This crosscut has been advanced 26 feet. Starting in vein porphyry it changed to a solid body of quartz of low assay value. There are spots that assay well. The south side of the crosscut looks more favorable and a south drift has been started therefrom with favorable indications.

On the 1000 level—the Rule drift—the upraise on the east side of the main drift, at a point 585 feet south from the shaft station, has been carried up 13 feet; total height, 50 feet, top in porphyry, clay and quartz of some value. From this point a north drift has been started and advanced 30 feet in porphyry and quartz. At a point 355 feet south from the main shaft a winze has been sunk 14 feet, and from this point a west crosscut has been advanced 12 feet. All these openings are in quartz, porphyry and clay formation of low assay value. We continue to do necessary repair work throughout the main shaft.

The *Enterprise* says: The crosscut 28 feet below the 1650 level of Con. Cal.-Virginia is progressing as well as could be expected. It is necessarily slow owing to the situation. There is no doubt in the minds of all the experts who have seen the situation but what a continuation of the ore body will be found when the crosscut has reached the distance required. The crosscut 14 feet above this cuts through 24 feet of ore, and it is not known how far above and below the 1650 level this ore body extends, as there has never been any work done in either direction directly above or below this locality.

The south drift on 1465 level of Ophir is in a softer formation of porphyry, showing lines of quartz. A small station has been opened in central tunnel at a point 56 feet at one tunnel, and prospect work will begin therefore in a northerly direction.

The upraise near mouth of west crosscut, 1465 level of Mexican, continues in a very soft porphyry formation showing fine lines of quartz. The Union Con. and Sierra Nevada joint west crosscut on 900 level, near north line of Union mine, is in hard porphyry.

In the Occidental from the west ledge above the 400 level they continue to extract about eight tons of ore per week of the average assay of \$44 per ton.

In the Kentuck the south drift from the east crosscut on the 1035 level is in 26 feet; the face is in quartz, with bunches of pay ore. 1200 level—The south drift from the Yellow Jacket incline is in 76 feet and continues in low-grade gold ore.

West Con. Va. & Cal.—During the past week the west crosscut run from a point 320 feet north of the shaft station on the 1100 level has been extended 30 feet and is now in a total distance of 788 feet. The face is in hard quartzite and the bow of water is unchanged.

On the 850-foot level of Belcher we have

cleaned out and retimbered 50 feet of the main north drift, making its total length 550 feet from the shaft. This drift has now reached the Crown Point line, and we have started a joint drift with that company to the northeast in quartz of a favorable character. A crosscut will be started in Belcher in a few days to the east for the purpose of exploring a body of quartz in this section of the mine. From the old stopes on the upper levels we have hoisted during the week 18 tons of fair-grade ore.

THE GOLDEN EAGLE MINE.—*Reno Journal:* The Golden Eagle mine, which is located five miles north of Reno, is producing large quantities of gold ore. From experiments made by mill process on several tons of the ore it is expected that all the ore from the mine will work from \$10 to \$15 per ton in gold.

The Reno Reduction Works have been leased to work 1000 tons of the ore. Concentrators will be put in the Reduction Works, as also gold saving appliances.

Lyon.

A RICH STRIKE.—*Virginia Chronicle:* A rich strike is reported in the Boston & Lester mine at Silver City. The mine is located near Oest and there is said to be \$10,000 worth of ore in sight. Pollard's mill will go to work on the ore to-morrow, and a \$4000 cleanup is expected to be made.

Nye.

THE NEW GOLD DISCOVERY.—The new gold field which has been discovered in the western part of Nye county, one mile north of Lone canyon, is in a gulch that heads near the summit of the range and washes into the great Lone valley. The country from the head of the gulch out into the valley has been prospected with good results in every case without getting down to bedrock. A correspondent writing to the *Austin Revue* from the new find says: "The range from Lone canyon, north to Gold Park canyon, 30 miles, contains hundreds of gulches in looks equal to Dry Gulch, and the chances are the prospectors will find four gold in them." The extent of the new find cannot be known for months.

BRITISH COLUMBIA.

YALE.—The trial made at Yale last week by Bell & McCastle's gold dredger fully realized the highest expectations of the prospectors. Working in 12 feet of water, gold gravel was pumped up from the bed of the river which yielded 19½ ounces of gold in a 36 hours' run. Stones weighing 25 and 30 pounds are brought up by the pump, and the whole machinery works perfectly.

MONTANA.

A RAUOLAR STAMPADA.—The excitement caused by the recent discovery of the Cayuse, a supposed rich gold mine 40 miles south of Glasgow, Montana, reached its climax last week, when 12 miners came in on horseback from Neilbar and over 50 men arrived from Canada and around Malta.

Fearing the strike would not be declared off, the miners from Neilbar started with a pack outfit. They secured fresh horses and started across the country.

John Cliff, a ranchman living 20 miles north of here, was drowned while crossing Milk river in the rush to get across. He, with others, attempted to swim his horse instead of waiting for the boat. The horses got jammed and he jumped off, and the swift current of the river carried away his body. The accident did not seem to put a damper on the others, for they rushed on to the gold fields.

The trains are bringing in large delegations of miners from Helena and Great Falls. From an old map of Kies the fact is developed that this was the old camp.

Everybody has thrown up his position to get a claim. Dan Sullivan, county jailer, has resigned his lucrative position to run a saloon at the mines. The miners have named the diggings Alexander City. The distance from Glasgow is 40 miles.

OREGON.

GRANT'S PASS COURIER: R. M. Kelly and W. J. Strong are doing development work on their copper ledge near the State line, six miles south of Waldo. The ore, of which there is an immense body, assays \$24 in gold, 17 per cent copper and \$12 in silver to the ton.

At both entrances to Tunnel Nine a huge vein of black quartz, resembling coal, crops out all the way along the tunnel, and there are large dumps of the ore at both ends. An expert, employed by J. C. Lewis, puts its average value at \$80 per ton. His is not the ordinary method of ore extraction, but a combination of chemical and liqnefying processes. Fifteen claims have been staked out in the immediate neighborhood, and the black vein has been traced over a wide area.

Three giants are running continuously on the Hampton-Lewis placer on Grave creek. The large force of men needed on the ditch construction has been paid off and the crew consists of ten hands. The ditch, which is 16 miles long, leaks more or less its entire length, as the blasting loosened the embankment dirt, so water will not be very abundant this season.

JACKSONVILLE TIMES: E. E. Miner & Co. are down 120 feet by their shaft in the Dardanelles mine and have run a drift in ten feet, where they have struck a ledge four feet wide, of decomposed rock. There are 150 tons of ore on the dump which assays from \$8 to \$50 per ton.

SOUTH DAKOTA.

GOLDEN REWARD CHLORINATION.—Black Hills Times: Herein is a brief description of the above method in use at the Golden Reward works in Deadwood, S. D. Before treating the ores they are assayed to find out their value in gold, then analyzed to determine the degree of heat and length of time required to roast them, also to determine the proper quantity of the different chemicals required to insure perfect results. All this is determined in the laboratory, after which the ore is pulverized fine

enough to go through a No. 8 screen. It is then roasted in Bruckner and White and Howell roasters. After roasting it is spread on the cooling floor, being assisted by the application of water. When sufficiently cool it is conveyed to the steel barrels, which are charged with the proper proportions of ore, chloride of lime, sulphuric acid and water. The barrels are then closed tight and revolved for the length of time which the previous analyses have determined to be needed. The chloride of lime, sulphuric acid and water generate chlorine gas, which, acting on the ore, dissolves the gold. The barrels are then stopped, water added, and the solution is filtered direct from the barrels into large settling tanks, where any remaining slimes left in the solution are settled. When the solution is clear it is pumped into the precipitating tanks, the free chlorine is driven off by the use of sulphuric acid gas, and the gold precipitated by hydrogen sulphuric gas. When the precipitation is complete the result is a mass of gold sulphides, which are then run through filter presses, the press retaining the gold sulphides and expelling the waste solution. Every week the gold sulphides are taken out of the press and roasted to expel the sulphur, then mixed with fluxes and melted into bright yellow golden bars, ready to be coined into golden eagles. The Golden Reward works, by the above described process, treat 100 tons of ore daily.

A CYANIDE SUCCESS.—Deadwood Times: The cyanide plant is now in full operation and all machinery adjusted, the Cornish rolls crushing the ore to 30 mesh. The movement of the rock is entirely automatic from the time it enters the mill from the ore bins to the bin containing the finished product. It is first broken in a powerful rock crusher, passing from it to the Bowers patent rolls (concave and convex), from which the pulp is carried up to a three compartment screen, then descending to the other sets of rolls, where the coarser particles are reduced. It is then again elevated to another revolving screen (steel 28-mesh), from which the finished product passes into the storage bins, loaded into cars and placed in the steel vats and leached with the proper solution. The works have now a crushing capacity of 50 tons per day. From the success attained by the company in the treatment of certain classes of Black Hills ore, there is no question but that they will soon have to double the present capacity of their works. The mines now owned by the company are fully capable of keeping the mill supplied, but in order to show the practicability of the method and its suitability, the management reserve a portion of the present capacity for the treatment of custom ores.

WASHINGTON.

Okanogan Outlook: The Bridgeport Mining and Milling Co. will equip their mine with a complete steam hoisting plant, consisting of a 60-horse power boiler, one Clayton air compressor, one hoisting engine, a sinking pump and two Ingersoll-Burleigh drills. They have also purchased a sawmill and will cut their own timbers and lumber for building purposes. They also propose to continue the development of the Columbia mine at the point where the work was done last season. The shaft, now down 150 feet, will be continued to at least the 300-foot level, and from this point drifts and crosscuts will be run to determine the width and length of the ore chute, and to tap the other veins which run parallel to the one on which the shaft is being sunk.

The placer mines on the Similkameen continue to yield a paying quantity of the yellow metal and new locations are being made every day.

The stamp mill recently erected at Camp McKinney is now running on ore from the McKinney mine. The ledge on this property has been prospected to a depth of 75 feet in several places, and the ore is invariably rich, in much of it the gold being free and plainly visible to the naked eye. About 15 men are at work on this property.

The Union Gas Engine Co.

The rapid advance of the gas engine within the past five or six years, and the strong hold that it has gained on the confidence of those who use motive power, is largely due to the ingenuity and energy of this company. From its swaddling clothes or creeping stage, as one might say, it has been brought by this company to full fledged manhood.

Where at one time, and but a few years since, it was regarded by many as quite improbable, if not impossible, that any high degree of power would be attained by these engines, it has been fairly demonstrated by the Union Gas Engine Company that a high rate of power can be furnished through this means, and at less cost than by the use of steam. While the engine has passed its experimental stage, and is now practically a perfect motive power, it is still the policy of the company to improve and adapt it to every possible requirement that it may be called upon to meet. The long list of names of those who are using the Union gas engines, both for marine and stationary purposes, is the best evidence that can be offered that the company's efforts have met with success. Whoever is in need of power, either for pumping, mine hoisting, propelling boats or anything else, should not fail to send for the finely illustrated catalogues giving full particulars. Address the Union Gas Engine Co., 221-223 First Street, San Francisco, Cal.

Coast Industrial Notes.

—Horses are being shipped from Union, Oregon, to Scotland.

—Two stamp canceling machines, with a capacity of 30,000 an hour each, are run by water power at the San Francisco post-office.

—The Bodie Gold Brick Consolidated Mining Company was incorporated yesterday. Directors—Charles Roberts, C. M. Sawyer, D. T. Meagher, R. H. Campbell, Martin Jones. It is understood Mr. Meagher is responsible for \$9,998,000 worth of the stock; each of the other directors has subscribed \$500.

—The Fulton Engineering and Shipbuilding Works, of this city, have completed and put in successful operation a new pumping plant for the Spring Valley Water Company at Black Point. The pumps will deliver 300,000 gallons of water to a height of 400 feet and are well adapted in every way to the important work.

—The understanding between the Panama Railroad Company and the Pacific Mail Steamship Company, by which the railroad company chartered the ships of the steamship company temporarily on the Atlantic side and ran them between Colon and New York under the name of the Columbia line, is at an end, and on June 15th the railroad company will put on other steamers.

—The construction of a tunnel to drain Humboldt lake, for the purpose of utilizing the water for irrigating the arid land in that vicinity, has begun under the direction of Southern Pacific engineers. The *New Era* says: The intention seems to be to drain a sufficient area to redeem 10,000 to 15,000 acres of land. By the end of the month twenty men and six teams will be engaged on the canal.

—“We are in no hurry to start up again at Roslyn,” said Manager Lytle of the Northern Pacific Coal Company when asked in regard to the situation at Roslyn, Wash. “At the meeting when the men refused to go to work at the new rate there were 46 votes cast in favor of accepting the reduction and 220 against. We have about 600 miners at Roslyn, so that the majority were ‘on the fence’ on the proposition. I guess we could open to-morrow if we wanted to, but we are in no hurry. The situation will remain as it is for about two or three weeks.”

—Articles of incorporation of the Overland Pacific Railway have been filed. The corporation will connect Fort Bragg, Mendocino county, and the Mount Vernon coal mines with railroad and telegraph lines. The new road will be built by way of the town of Willits, with a branch line from Willits to Ukiah. The directors are Barclay Henley and T. L. Johnson of San Francisco, Calvin Stewart of Fort Bragg, G. W. Hunt of Walla Walla, Wash., and R. S. Straban of Portland, Or. The capital stock is \$2,510,000, of which Directors Henley and Johnson have subscribed \$54,500 each, Director Hunt \$800, and the other directors \$100 each.

—The following are recent new incorporations:

Coast Development Co., San Francisco. Capital, \$50,000.

Pacific Stethophone Co., San Francisco. Capital, \$600,000.

Latham, Schroeder & Co., San Jose. Capital, \$30,000.

Artesia Drug Co., Hanford, Kings county. Capital, \$10,000.

Yellowstone Mining Co., San Francisco. Capital, \$100,000.

Ukiah Mutual Building and Loan Association, Ukiah. Capital, \$1,000,000.

Kern County Fruit Exchange, Bakersfield. Capital, \$25,000.

Teredo-Proof Plie Company, San Francisco. Capital, \$100,000.

North Stockton Improvement Co., Stockton. Capital, \$15,000.

Riverside Abstract Co., Riverside. Capital, \$62,000.

San Diego Co-operative Manufacturing and Mercantile Association, San Diego. Capital, \$100,000.

California Ground Electric Co., San Francisco. Capital, \$100,000.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-tightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.

FRUE ORE CONCENTRATOR

OVER 8200 IN ACTUAL USE.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.
" " Improved Belt Frue Vanner..... 800, f. o. b.
" 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

SAN JACINTO ESTATE, LIMITED,
Office of General Manager,
P. O. Address, South Riverside, San Bernardino Co., Cal.
CAJALCO, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
I am, my Dear Sirs, Yours faithfully,
S. HARRIS, Manager.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.

UNION GAS ENGINE CO.

Pioneer Manufacturers

OF GASOLINE ENGINES AND OWNERS OF TWENTY PATENTS ON SAME

Engines for Mining Purposes a Specialty.

WARNING! If you are in need of power for mining purposes investigate this engine and take no other. Many so-called gasoline engines are now on the market, which are direct infringements of our patents and it is our intention to bring suit against the various infringers. As the law holds the purchaser, as well as the manufacturer, we would advise parties who have already purchased other gasoline engines to obtain from the sellers of such engines a good and sufficient bond protecting themselves in case damages are obtained against them, as it is not the policy of this company to work a hardship on innocent parties, but the law makes no such provision.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED } CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. { FRANK BARREBE, }
{ Sept. 19, 1893. } { Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 130 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILE IN OPERATION CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW ORE CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.
Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.
Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 1/2 per cent; from East ledge, * * * a saving of 92 per cent.
The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

The Miners' Drilling Contest.

"Miners' Day" was celebrated at the Midwinter Fair last Tuesday. The principal event of the day was the drilling contest, at which \$1000 in prizes were awarded. The rules of the contest, heretofore published, were observed, and considerable interest was manifested. The judges were G. W. Grayson, Aug. H. Schnabel, Chas. F. Hoffman and Felix Chappelet. Lieut. A. M. Hunt was the timekeeper. This was the first rock-drilling contest on the Pacific Coast. At the Denver contest last year the

world's best contest was made, D. L. Jones, of Colorado, holding the single-hand record, by sinking a hole eighteen and eleven-sixteenths inches deep in fifteen minutes. Page and Reagan, of Butte City, Montana, held the double-team record, drilling twenty-nine and fifteen-sixteenths inches in that time. Ahern and Rinker, of Denver, beat that time, they drilling a hole thirty-one and three-eighths inches in fifteen minutes. Mr. Ahern had the record of drilling single-handed eighteen and three-eighths inches in fifteen minutes. He, John Coan and E. F. Durham entered for the single-hand prize. The other entries in that contest were A. Phillips, of Sutter Creek, Amador county, G. J. Martin, of Amador, and G. M. McGowan, of Silver Creek, N. M. The drilling began at four P. M. Spots were marked on the granite blocks where the holes should be drilled, and positions were taken by drawing numbers from a hat. Platforms were built flush with the granite, to make the conditions as natural as possible.

E. F. Durham, of Grass Valley, took the first prize of \$200, and the world's championship, drilling a hole nineteen and thirty-one-thirty-seconds inches in fifteen minutes. T. J. Ahern, of the same place, drilled nineteen and nine-sixteenths inches and took second prize of \$50, both he and Durham breaking the former record.

In the contests for the double-team drilling, John Kitto and Sam Harvey, of Amador, put a hole down thirty and twenty-one-thirty-seconds inches and took first prize of \$200. P. Feeney and J. Lynch, of Grass Valley, took second prize, drilling twenty-seven and five-thirty-seconds inches. Messrs. Coan and Jefford, the third team, drilled seventeen inches.

In the triple-team contest, Messrs. Jordan, Kennedy and Woods, of Grass Valley, worked a few minutes and quit, not having practiced together. Messrs. Dingle,

Kitto and Harvey, of Amador county, put a hole clear through the forty-inch block of Rocklin granite, and had about two inches started on a second hole when their quarter of an hour was up. They got first prize, \$300. Messrs. J. Feeney, P. Feeney and J. Lynch, of Grass Valley, drilled almost through the forty inches of granite in the fifteen minutes, and took second prize of \$150.

The prizes were all paid immediately at the close of the contest.

DURING the twenty-five years since the completion of

COMBINED PATENT FRICTION DRUM AND BRAKE AND REVERSIBLE LINK MOTION HOISTING ENGINE.

the Central Pacific and Union Pacific railways there has been brought across the continent to this city by rail 1,573,700 people. During the same period 1,036,600 were carried Eastward.

NEARLY \$25,000,000 in gold has been shipped to Europe since April 1st, and Secretary Carlisle talks of issuing another block of bonds—to get more gold to go to Europe. The Secretary, as long as he is there, can issue bonds just as fast as gold can be shipped away. It's a big thing—for the shippers. Of course, there's no business about it, but, then, there isn't much business about anything that Mr. Carlisle does, so far as the Government's interests are concerned.

THOUGH early to discuss the benefits derived from the Midwinter Fair, yet it is evident that the exposition has had a beneficial effect on our mining industry. Our local manufacturers and others have made good exhibits; the display of the several counties has been complete, and practical results are directly traceable to what has been seen and learned by the admirable exhibits of our mineral resources and mining machinery.

Hoisting Engines for Mines.

The engraving shows a combined friction drum and brake, and reversible link motion hoisting engine, with spirally-grooved drum, built by the Lidgerwood Manufacturing Company, 96 Liberty street, New York City, specially adapted for mines, inclines, etc.

This is a combination for either double or single compartment shafts or inclines, as it unites the qualities of the reversible and friction-drum engines. In a single shaft all the hoisting of ore, etc., may be done by the engine in the

usual way, and the empty car and cage, or bucket, lowered by means of the brake; while for hoisting and lowering the men the drum may be thrown into gear and the engine used as a reversible engine, handling the load by steam. After starting the load the link can be hooked up, cutting off the steam at any point of the stroke desired, thus doing most of the work by its expansion in the cylinders; while in lowering by means of the friction drum and brake the engine does not run and of course uses no steam. A special feature of this style of engine is that while designed mainly for single-shaft work it can also be used for a double shaft by simply throwing the friction into gear permanently and using it as a regular reversible link motion

engine, hoisting load and cage in on shaft and at the same time lowering the empty car and cage in the other shaft. The reversing, friction and brake levers are all assembled in a rack in front of the engine and operated by means of thumb latches, with notched quadrants, so that they will remain wherever placed. This arrangement of levers makes it easy for the engineer to operate the engine quickly, safely and without fatigue.

By an almost unanimous vote the Miners' International Congress in session at Berlin has resolved that mine proprietors should be held responsible and be liable for damages for every accident to any mine employe while at work in or around the mine. The British delegates opposed the resolution. The vote was a mistake. Where disaster results from bad management, insufficient or defective appliances, etc., the owners should be responsible for damages; but where carelessness or foolhardiness results in accident or death, the owner should be held guiltless. Of all places on earth, a man in a mine must look out for himself, and others, too, to prevent accident, and constant care alone can prevent loss of life or limb.

UTAH'S chances to be the forty-fifth State are increasing. The House bill providing for the admission of the territory to Statehood was favorably reported from the Senate Committee on Territories on Thursday, and was placed upon the calendar. The bill directs that the election for a constitutional convention be held on the Tuesday after the first Monday in November, 1894; that this convention shall meet on the first Monday in March, 1895, and that the constitution framed by the convention shall be voted upon, and the election of State officers and members of the State Legislature under it shall be held on the Tuesday after the first Monday in November, 1895. It is considered probable that the bill will pass both houses this session.

A BILL has been introduced in the House amending the act incorporating the Maritime Canal Company of Nicaragua. The bill provides that the stock of the company shall consist of 1,000,000 shares at \$100 each. The Secretary of the Treasury is to subscribe for \$70,000,000 of the stock of the company, and pay for it at par by the issue of United States notes. The stock so issued shall be full paid and non-assessable. Six million dollars of the stock is to be issued to the Government of Nicaragua, and one-half million dollars of stock to the Government of Costa Rica, according to the terms of their respective concessions heretofore made. Of the remainder of the stock (\$22,500,000), \$7,000,000 is to be issued to persons and corporations designated by the company, and the remainder of the stock is to be deposited in the treasury of the company until Congress shall decide whether it desires to purchase it. In consideration of this act the company is to call in and cancel all the stock heretofore issued. To secure the proper application of the money authorized, the incorporating act is so amended as to provide that the board of directors of the canal shall consist of eleven persons, eight of whom shall be appointed by the President.

An Object Lesson.

Though England produces no silver, nor her colonies to any appreciable amount, yet the silver question has such extensive connection with commercial affairs that English interests are alert to existing and probable conditions should English policy continue to dominate and compel the continued demonetization of the white metal. The fact that the United States continues to take its policy from England and that New York and Washington wait to see what London wants before obeying the high behest does not alter the workings of natural law, which like gravity is a constant force.

If there is one thing more than another in which England considered it had a monopoly, it is tin. England suddenly discovers that it has serious competition, and that the present low price of silver is an important factor in a present pressing problem. In '87 the production of tin in the Straits Settlements was 23,814 tons; in '93 it was 39,944 tons; in '87 the average price paid to the Chinese miners there was \$486 per ton; in '90, \$554 per ton; in '93, \$634 per ton. Up to two months ago—our latest advices from there—the Chinese miner was getting \$649 per ton for his tin.

These figures show that since '87 the production of tin in the Straits Settlements has increased about 70 per cent, and the still more startling fact (from an English standpoint) that, notwithstanding the unusually low price for tin in London, the Chinese miner in the Straits Settlements is to-day getting nearly 18 per cent more for his tin than he was four years ago, in the face of the fact that the English tin miner is now getting twenty-eight per cent less for his tin.

The explanation is in the relative value of silver. The rate of silver fixes the rate of exchange; silver is way down as compared to former years; so is the rate of exchange, which is now 2s. 0½d. per dollar, and the tin mine owner in the Straits Settlement is in clover like unto the clover that it was predicted at the last presidential election we would be in here. Every pound sterling sent him now nets him ten dollars; in '88 it only netted him six dollars. The farther silver drops the lower the rate of exchange; the lower the rate of exchange, the better for the tin men in the Straits Settlements; the better for the tin men in the Straits Settlements the worse for the tin men of England. It means utter ruin to tens of thousands of English families. There are other things besides chickens that come home to roost, and English mining interests are very much disquieted as they realize the facts here briefly sketched, and which are portrayed at length in the London *Mining Journal* and other reputable sources, and the worst of it is that, no matter how low adverse British and American legislation may force silver, the lower the better for England's competitor in mining tin. Were silver to drop to a shilling an ounce, the Straits Settlements could still sell tin in London at one-third the present price of tin and make a profit.

These facts constitute an object lesson. It may be that their realization will compel the foreign power to which our country's present masters bow the knee in humble though blind adoration, to change its tactics. If so, of course, the United States will hasten to follow suit. The matter has long since ceased to be a question for college professors to determine, and now, when the low price of silver is threatening the commercial supremacy of our most formidable business rivals, self-preservation may impel her to move in the rehabilitation of that precious metal.

DELEGATE JOSEPH of New Mexico has introduced a bill to authorize the exploration and purchase of the mines within the boundaries of private land claims in all Western States. The bill, if it becomes a law, will give any citizen of the United States qualified to make entries of public land the privilege of entering upon any territory embraced within any land claim confirmed by the Court of Private Land Claims and in taking up a mineral claim. Before making such claim the locator must tender the owner of the land \$2.50 per acre for it.

THE New York and Boston newspapers say that the banks are doing all that they can to continue the run on the \$100,000,000 gold reserve, to induce another issue of 5 per cent bonds. 'Tis probable that such result will come about independently of any action the banks may take. Under present conditions depletion of the country's gold goes on in accordance with the operations of natural law. At present the banks of this country can neither help nor hinder the foreign gold drain.

It is believed that when the Mendocino county coal mines are tapped as proposed, by the Overland Pacific, a good quality of steam coal can be laid down here for less than \$4 a ton, which would be a boom to local manufactures.

Gravel Formation.

A Nevada correspondent writes from Reno disputing the ordinarily accepted theories of ancient river channels. He takes no stock in the old river channels. He says he has studied this matter during the course of a long and active life and is of the firm belief that "there is not an underground ancient river channel on this continent." He continues:

I find in going east and west on the different ridges that the bed-rock keeps changing and each stratum has its own peculiar character of gold and gravel, for I have followed them for miles in a northerly and a southerly direction from ridge to ridge. All mineral in belts, as the great slate range of California, is put up in this way, averaging from 1000 to 1500 feet. Men who went up to the Frazer river in response to inquiries about the slate belt told me that the river ran through granite until it came to a bend, where it turned northerly where Thompson river came in, and on Thompson river was slate rock and the first coarse gold that they found. I came to the conclusion that it rises north, nobody knows where, until it comes to the great bend and then through granite to the coast. It evidently comes from the north and keeps between the granite and slate; then the slate belt runs south until it goes into the ocean.

The theory of primary formation is thus elucidated. This earth was once a globe of fire; the waters were a mist and only settled as the earth cooled, and the primary rocks formed in a line in a northerly and southerly direction for a period of time and then there was an eruption. Then came the second cooling and the formation of the secondary or the light-colored rocks and the mineral formation; then primary rocks being shattered into fragments, large masses formed mountains, and small fragments all floating, and thus was formed the boulders, like throwing particles of ice into water. The corners would melt off first and form round, smooth boulders; and as the waters settled, they had the action of the heat and the water combined, for the water covered the whole earth, and all these gravel deposits were formed under the ocean instead of ancient river channels. I believe in the theory that all mineral is held in solution in the ocean, and it would be natural for the mineral to settle first, that being the heaviest; and the heat being greatest in the fissures, and attracted by the heat, the mineral and quartz were deposited and formed ledges, and the heat being so great, the ledges practically melted down and with the action of the water formed the beds of gravel as we now find them. That is the way I account for the large nuggets of smooth gold deposits that we find all over the country. In ledge mining one does not find nuggets of smooth gold.

A mineral belt is the same character of rock, running through the country, and in general has three distinct veins, but one always takes predominance over the others and this one sometimes will hold nearly all the mineral. This occurs in gravel mining as well as in ledge mining.

As one goes east and west the character of the gravel changes, as well as the gold and bedrock from ridge to ridge. I don't want to be understood that the pay gravel is continuous. It is frequently cut off by the hard rock or primary rock; for sometimes a good lead will be cut off or rimmed with the hard rocks. It is, therefore, sometimes cheaper to take them in the end and follow them in than to cut through the rim rocks. My old stamping ground for a good many years was on Liberty Hill, Nevada county, near the Hornblende range, which always produces coarse gold, as at Forest Hill and other places. This belt takes more the form of basins than the slates proper, as is the case mostly with the granite belts; that is, the granite belt gravel deposits are generally in basin form. I don't go a cent on ancient river channels. Maybe some time in the next century what I have written can be proved to anybody that will investigate. I know it is hard to get over what geologists teach, but men learn sometimes by experience things that are not in books.

This matter has been thoroughly argued, and though it is not likely that the verdict will be ever unanimously accepted as definite, it is well established that the ancient river channel theory accords better with existing facts than any other one advanced, and approaches the exactness of a mathematical demonstration.

An Opportunity for Inventors.

The commercial value of an idea would be considerable to the clever inventor who can devise a durable wheel for an electric car. A cable-car wheel will last a little over a year, but there is no determining with any certainty how long a wheel will last when used on an electric railway operated by the trolley system, where the electricity goes back to the power-house through the track. A comparatively new wheel will be found to be devoid of rim or edge while its companion wheel, put on the same day, will be as good as the first time it revolved. No one has been able to find out the reason or remedy for the singular defect. Keen wits are at work on the problem; there is tremendous loss by reason of the present imperfection, and tremendous gain to the man who can remedy the existing defect in the system.

Our Mineral Resources.

The mineral product of the United States for 1893 aggregated in value \$609,586,083. Of this the non-metallic product is \$358,604,217 and the metallic, \$249,981,866, leaving \$1,000,000 unspecified. This is the smallest for five years, and is \$75,000,000 less than the previous year. Petroleum gained \$3,000,000 in valuation; gold gained \$2,950,000 in the value of the product, as compared with the preceding 12 months; silver gained \$2,585,857, taking its coining value as the standard; copper decreased in production 16,000,000 pounds and in value \$5,985,478; lead decreased about 50,000 tons and \$5,000,000; zinc decreased about 9000 tons and \$3,000,000; aluminum increased 80,000 pound and \$94,000; nickel fell off about 50 per cent in quantity and value.

General Mining Notes.

LAST month's yield of the Utica and Stickle mine was \$347,000.

THE Eagle Bird mill, near Nevada City, Cal., is to be started up again.

SUPR. WILSON, of the Elkhorn Mining Company, reports that the profits for April were \$14,691.

A ton of ore has been struck in the Spotted Horse mine, Montana, some of the ore running \$3000 to the ton.

THE Tamarack Copper Mining Company has declared a dividend of \$4, payable June 20th, making a total of \$3,870,000.

THE North Star Mining Company will increase its capital stock from 100,000 shares of \$1,000,000 to 200,000 shares of \$2,000,000.

MINERS, it is said, are offering their services for \$1.50 per day at several camps in southern Yavapai, Arizona, reports the *Journal-Miner*.

THE National Lead Company has declared dividends of one per cent on common and 1½ per cent on preferred stock, payable June 15th.

A ROCK weighing \$500 was recently received at San Quentin from a quartz mine at Los Tules, Lower California, the result of a few days' run.

THE Boston & Montana Consolidated Copper Mining Company has declared a dividend of \$1, payable June 28th, making a total of \$2,225,000.

THE Omaha Mining Co. has declared a fifteen-cent dividend, its twenty-sixth. Superintendent Mainhart says the mine looks fine. It is a good property.

THE ocean beach near Ocota, Washington, is reported alive with men and boys panning out flour gold from the sands. They claim to be realizing something worth while.

PLACER mining on the Similkameen has been suspended by reason of the spring rise. There may be more gold taken out of the swift river this year than for 30 years past.

FROM Cripple Creek, Col., is reported a discovery of sylvanite ore at a depth of 85 feet, which runs \$150 to the ton. About 100 pounds were taken out. The vein is from two to four inches thick.

A RICH strike is reported from the New Brunswick gold mine in Blacktail park, fifteen miles south of Butte, Montana. Some of the quartz taken out at a depth of sixty feet is said to assay \$18,000 per ton.

THE *Denver Record* says: "Placer mines along Clear creek near Golden are washing out from \$1 to \$4 per day per man. The crudest methods known to placer mining are used in obtaining the gold."

IN the *Culinary Engineer*, Prof. Lakes says that a resurrectionist would have a profitable profession in West Africa, for there are millions of pounds worth of gold buried in the graves of chiefs and principal men.

DOING the last year Arizona has made greater progress in the output of gold than it has in the previous ten. Now it begins to look, says the *Journal-Miner*, as if the yield for 1894 would amount to \$5,000,000.

IN Gold Field, 40 miles easterly from Phoenix, Arizona, Hall & Sullivan are running their 20-stamp mill on Mammoth ore, and turning out \$50,000 per month. This mine was reported to be a fake about a year ago.

KINZIA LANNIE, an old-time assayer and mill man, is in Spokane, where he has just completed the smallest gold mill ever made in the West. The complete outfit weighs 40 pounds and the millsite is a big arm chair.

SUPR. CLARK of the Poorman mine, Idaho, wrote the board of directors that he had effected changes in the treatment of the ore that would cause a saving of \$5 per ton, whereupon they rescinded the recent assessment.

A BILL has been introduced in the Legislature of Ontario, with a very reasonable show of its passage, exempting from Government royalty forever all mineral locations made in the province for the next five years.

THE question that puzzles the Colorado *Mining Gazette* is, How the Georgetown Coney Home Reserve fellows figure that the issuance of \$500,000,000 in irredeemable Government bonds will benefit the silver miner?

THE Utica and Stickle mine has what are believed to be the largest chlorination works in the world—five furnaces of 22 tons capacity per day. The cost to reduce the sulphurets to bullion bars .22 fine is placed at \$5.50 per ton.

DIACROTA PASTON of the United States Mint estimates the world's production of gold for 1893 at \$152,439,207, of which the United States contributed nearly \$36,000,000, Australia and South Africa following in second and third positions.

AN Arizona paper says: "The time is now ripe for the yearly discovery of rich gold rock on the desert hundreds of miles from water. Beware of the desert finds in summer and the discovery of rich mineral in the ice-bound mountains in winter."

W. C. RALSTON and associates are running the Quincy hydraulic mine in Plumas county. A gold bar valued at \$2080 was received this week, being a one-third cleanup of an eighteen-days run. This is believed to be the largest hydraulic mine now running under the Caminetti law.

THE James Kennedy group of gold mines at the camp of Kennedy, Humboldt county, Nev., have been sold to a San Francisco company, represented by Jim Wardner, of Coeur d'Alene, for \$75,000. A 20-stamp mill will be erected within 60 days. One hundred and twenty miners are now there.

THE receipts of gold at the United States Branch Mint at Denver for May up to the 10th inst. show an increase over the same period of 1893 of 400 per cent. The gold received from the stamp mills and placers, in the form of nuggets and retort, gives an increase of 137 per cent, showing that the greater increase comes from the smelting product.

THE famous Gwynn mine of Calaveras county, a gold-producing property which has a record of having paid its owners something above \$2,000,000 in dividends, is soon to be reopened, says the *Stockton Independent*, by capitalists who are confident

of restoring the mine to its place among the leaders of the State. The mine is located on the Mokelumne river, about 60 miles from Valley Springs. The property is now in the hands of a corporation formed to work it, and is held under a contract of purchase which gives the company two years to pay for the mine. The purchase price is \$200,000, and the deed is in escrow.

THE recent average battery assay of the Hale & Norcross ore milled at the Brunswick mill (749 tons 769 pounds) is reported to be \$18.15; percentage obtained of the average battery assay, 89.24-100 per cent. The standard value of the bullion yield of this ore is: Gold, \$4077.80; silver, \$8059.46; total, \$12,137.26, the net value of which, melting charges deducted, is: Gold, \$3916.91; silver, 6233.49 100 fine ounces.

THE Mgalia gold mine in Butte county is about to pass from the hands of N. D. Rideout into the possession of a stock company capitalized at \$1,000,000. The subscription books open at the Anglo-California bank to-day. Col. Frank McLaughlin will be general manager, and as an investment the enterprise is looked upon with favor. Gov. Markham, Henry T. Scott, I. C. Stump, Jas. L. Flood and other prominent men will act as directors, when the allotted number of shares—60,000—are subscribed for. Mr. R. M. Higgins, the secretary, room 1, ninth floor, Mills building, can furnish all required particulars.

REOAUINO the Con. Va., the *Enterprise* says that the bonanza development below the 1650 level shows it to be even better than has been represented, especially in the lower south drift, 28 feet below the level or 14 feet below the original bonanza drift. The first two feet of the lower drift from the west crosscut were in low-grade ore, but the last 19 feet passed through ore averaging \$60 per ton, and the face of the drift shows ore worth over \$100 to the ton. There is every reason to suppose from the character of the ore and the vein itself that it will extend twice as far south as that in the upper drift, as it shows great strength besides being fully as rich, assays going as high as \$500 and \$600 to the ton. It is a continuation of the ore body above, and how far it extends downward has to be found out.

THE following are recent mining incorporations: The Bear Lake Consolidated Mining Co., limited liability, at Victoria, B. C. Capital stock \$500,000, with shares at \$5 each. Incorporators—G. Riley, G. Leiser, M. Gutmann, G. Hunter and G. Nowell.—The Civil Service Gold Mining Co., at Boundary City, Wash. Capital stock \$100,000, with shares at \$1 each. Incorporators—Wm. M. Pinkston, W. W. Davy and B. F. Budd.—The Hope Extension Gold Mining Co., at Basin, Mont. Capital stock \$400,000. Incorporators—A. H. Mitchell, W. Mackey, G. H. Tong, L. Eaves, E. A. Nichols and C. E. Rivers.

Our Cup of Gold.

With a beautiful reference to the Biblical story of Joseph and his brethren, Thomas Starr King once spoke of California's "autumn sack" as "stuffed with grain, while the month of it contains a cup of gold."

IN this striking metaphor, says the *Bulletin*, the eloquent orator associated the two great industries of the State—agriculture and mining. The autumn sack will not this year be greatly distended with grain, but the cup of gold from the mines will be larger than it was in 1893, when the wheat harvest was hountiful.

THE gold product of the State is likely to show an increase of \$2,000,000 this year. Last year it was about \$12,500,000. The output of the yellow metal for 1894 will at least be \$14,000,000, if the present rate of production be maintained.

THE year has witnessed a genuine revival in quartz mining. This applies especially to Calaveras county, where the wonderful richness of the Utica mine has made almost any sort of fair prospect salable at a good price. Many mines in the neighborhood have been doubled in market value by the developments in the Utica.

THIS remarkable mine has for some time been the chief gold producer in the State. It has this year doubled its yield. Its monthly product is about \$200,000. Last year it turned out \$100,000 a month, and that was regarded as a great yield. It is said, on good authority, that recently the mine turned out \$200,000 in a run of six days, which is at the rate of \$1,000,000 a month.

THE Utica is owned by Alvinza Hayward, the Hohart estate and Mr. Lane. This is strictly a private property, and it is scarcely necessary to say that there is no stock of the company for sale. In fact, while the output of the California gold mines continues to run well up into the millions, there is no stock gambling connected with any of them at this time. Even Bodie stocks are now little subject to Call Board speculation, though the district is still productive, its annual output being in the neighborhood of \$300,000.

WITHIN a year a number of French capitalists, composing the La Grange Mining Company, have invested nearly \$1,000,000 in Trinity county. The company recently bought what is known as the Hayes mine, consisting of half a dozen gravel claims strung along the Trinity river for a distance of two miles. The price paid is said to have been \$185,000. The property includes a ditch carrying 2000 inches of water. Not content with this large supply, the company is constructing another big ditch at a large cost. The company is operating with good results what used to be known as the Loveridge mine. As the debris from the washings is discharged into the Trinity, thence flowing into the Klamath, which empties directly into the ocean, there is no restraint on its operations through fear of damages to agricultural lands. For this reason hydraulic mining in Trinity county is flourishing, while on the watershed of the Sacramento the industry has diminished to but one-tenth part of its former proportions.

CHARLES G. YALE, statistician of the Mint, says that the demand for California gold quartz mines is greater than it has been for the past 20 years. He looks for an increase rather than a decline of the present activity in gold mining.

General News Notes.

RISEING AWEBS wreaked ruin in Pennsylvania during the week.

SENATOR HILL of New York is fixing up a little tariff bill of his own.

IT is expected in the Senate that the tariff bill will be passed before June 15th.

A WOMAN with a baby has "earned" \$15 a day haggling in Golden Gate Park.

GOV. WAITE wants Mexican dollars coined to be used as legal tender in Colorado.

GOVERNMENT VAULTS now contain \$790,826,660; a year ago they held \$756,544,116.

SANATOR JOHN P. JONES of Nevada will shortly issue an address on the silver question.

THE entire town of Manchester, N. J., was sold at auction last Wednesday, in foreclosure of a mortgage.

KELLY says that when he gets to Washington he'll keep off the grass, and deliver a speech from a balloon.

JOHN PRICHARD, superintendent of the Dening mine, near Black Diamond, Washington, was killed by a car last Tuesday.

THE bituminous coal strike still continues. Pennsylvania mine owners intend to employ outside men, and further trouble is feared.

TWENTY-DOLLAR PIECES which have been hollowed out and a plate of brass inserted, are making their appearance in the foot-hill towns.

WHEAT has dropped to fifty-three cents in Chicago, the lowest in seventy years. The simultaneous drop in silver is doubtless "a mere coincidence."

THE American Railway Union is being introduced in Los Angeles and the employees of the Southern Pacific railroad are joining it in large numbers.

AS NEAR as can be figured among the daily fluctuations and amendments in the tariff bill, the probable annual income from the bill will be \$61,977,862, as against \$77,644,188 from the McKinley bill.

ON the 20th ult. there was in European banks \$1,766,100,000 in gold and silver; on the same date last year there was \$1,631,200,000. Of this amount there is \$120,000,000 more gold than one year ago.

HIGH-WATER MARK has been reached on the pension business. From now on the payments will be less. Pensions have taken about forty-eight per cent of the entire income of the Government since July 1, '93.

GENERAL SUPERINTENDENT JAMES E. WHITE of the U. S. Railway Mail Service has decided that all railway postal clerks must accept matter offered them at the cars on which postage has been properly paid.

COGNACUS VANDERBILT and thirty other New York millionaires have opened a loan office. Money will be loaned on personal property for the full value of the goods pledged at the rate of one per cent interest per month.

THE Bimetallic Convention, now in session at Washington, has adopted a resolution in favor of the free coinage of silver in the ratio of 16 to 1, and declaring support only to candidates who pledge themselves to vote for free coinage.

THE conductors and motormen of the Atlantic Railway Company, in Brooklyn, failed to array themselves in new summer uniforms last Sunday, and the entire system, embracing eleven lines, is tied up and 1000 men are out of employment.

THE Populists nominated J. V. Webster of San Luis Obispo for Governor at Sacramento last Wednesday. The Prohibitionists have nominated Henry French of San Jose for that responsible office. The entries have not all yet been made, however.

THE general report is that on the occasion of the recent stage "hold up" near Angeles there was only bullion to the amount of \$15,000 aboard. It transpires, however, that there were five bars of bullion, worth \$30,000 each, and some chlorine gold, making a value of \$178,000, being two weeks' cleanup of the Utica mine.

JOSEPH PIAACE, an American citizen of Meriden, Conn., has been in this country since he was ten years old, served through the Civil War, and is now on the pension rolls; but as he was born in Canton, China, he has been ordered by the Internal Revenue Collector of Meriden to register as a Chinaman under the Geary act. Joseph objects.

FOR the first time in the history of the Grand Trunk railway of Canada, all of its shops and machinery are idle and the 1200 mechanics employed by the company are walking the streets with nothing to do, and there is not likely to be a change for the better until a settlement of the coal-miners' strike in the United States has been reached.

COXEY, Browne and Jones have been sentenced to twenty days in the Washington, D. C., jail for displaying a banner in the Capitol grounds. Coxey and Browne have also been fined \$5 each for walking on the grass in the Capitol grounds. Coxey has issued a bulletin asking for money. The "Industrials" at various points are still tussling with railroad companies for free rides.

Personal.

W. F. ENOLEBRIGHT, of Nevada City, is attending the Champion-Wyoming trial.

MASTIN W. MURRAY, a well-known mining man, has lost his reason. He was formerly with Capt. Carroll, and made considerable money in mining and speculation.

JUNOE GOONWIN, of Salt Lake, Utah, is in the city. Talking of matters and things in an interview he says: "At present we are deeply interested in the Mercur gold district. Those who claim to know say that it contains more gold than all the gold fields of South Africa. The district is only two and one-half hours' ride from Salt Lake, and many people have flocked into the valley. The gold is in a queer formation, extending over miles of country. It is probably a sedimentary deposit at the bottom of what was probably an old lake. Many people are very enthusiastic at the prospect of seeing the district turn out big fortunes in gold. The gold runs from \$8 to \$20 a ton. It is certainly a rich deposit."

Milling Free-Gold Ores.

TO THE EDITOR:—The various articles which appear from time to time in your paper on quartz mills and milling are very interesting and instructive, and I think where fair comparisons are made the results are generally in favor of California milling or rather in favor of the system of medium weight stems, a short drop and a quick one, as against the long and slow drop with a light or heavy-weight stem. But there are many other conditions to look after in order to do good work in free-milling gold ores, such as the grade of the plates, height of the discharge (i. e., the elevation of the bottom of the screen above the top of the die), size of the screen, whether or not inside plates and splash boards are used, time of putting in quicksilver and amount used, condition in which plates are kept, etc. All of these conditions affect the loss or saving of quicksilver, which is the agent used to save the gold, and if silver is lost most assuredly gold is carried away with it, and how easily a pound of silver can carry away an ounce of gold. Too little attention is paid to the loss of silver and the reasons why. If the loss of silver is nominal in thorough amalgamation, then the tailings will carry but little if any value whatever in the form of free gold or particles of amalgam.

Mr. Paul states, in his article in your issue of April 28th, that he does not think there is a mill using stamps, silver plates and concentrators only that does not run away in the slimes and tailings from 20 to 35 per cent of the assay value. If he had said from 15 to 40 per cent he would be nearer right, because there are some mills which do not save over 60 per cent, and the mills that work 85 per cent are few in number, though it is very possible to work as high as 90 per cent, but it requires conditions not carried out in the majority of the mills. Mr. Paul speaks of the results from tailings at the mills of Johannesburg, South Africa, and gives figures for 1893 and 1894. His figures, however, do not convey any information as to the value per ton of tailings. I will follow with some figures deduced from the report of the Robinson gold mine of Johannesburg for the month of February, 1894. Ore crushed during a run of 27 days and 12 hours with 60 stamps was 7912 tons, the gross receipts for the month were \$246,128, or \$31.10 per ton, divided as follows:

Free gold, \$20.50 per ton.....	\$161,328
Gold from chlorination of sulphurets.....	61,812
Gold from mill tailings, 5225 tons, worked by the cyanide process, \$4.86 per ton.....	24,424

Now, calculating that from one loss or another, such as leaky vats, insufficient strength of the cyanide solutions, carelessness of employes and unfavorable conditions of the ore, for all ores are not subject to the cyanide treatment, they worked their tailings to 85 per cent of their value; then their loss, after all of the above treatments, was 86 cents per ton. Without the cyanide working of the tailings their loss would have been \$5.72 per ton, and that in an improved American mill with the best of California mining and milling men connected with the property, Herman Jennings, H. C. Perkins and Thomas Mein being among the number, which shows how much we are constantly running away with our tailings.

Mr. Paul is right in his estimation of the cyanide process, and it will only be a short time until all mills, where the conditions are favorable, will work their tailings with cyanide, but it is not applicable to ores carrying lead, zinc, copper, antimony, and coarse gold. The presence of lime is a help. Therefore it results that stamp mills must be depended on for relieving the majority of ores from the gold they carry. By making the saving of gold the first consideration and the amount crushed second, the best results will be attained. And the only way to make a success is to keep pace with the times, and if your neighbor adopts a new idea don't condemn it because you did not think of it, but try it and, if good, adopt it. Too many are apt to think there have not been any improvements made in gold-saving devices and improved methods of amalgamation, and they go right along running gold away with their tailings. Of course, everybody has his own ideas about weights of stems, shoes, dies, etc., length of drops and the number per minute; and if different millmen would contribute articles on their experience, we would know what our neighbors are doing and soon find the happy medium.

In support of my figures showing 85 per cent as the result of cyanide on the tailings, I will quote the Mercur mine of Utah, where they work the ore entirely by cyanide, the ore presenting the most favorable conditions for working, and with two or three years' experience and the best skilled labor to be had, they work it to 90 per cent of the assay value.

C. S. RICHARDSON.

Grass Valley, Cal., May 16, 1894.

In the suit in Amador county, this State, between the Keystone and Spring Hill mines, Judge Davis has made a ruling admitting the South Spring Hill to enter the Keystone mine, inspect and survey it, etc.

History Repeating Itself.

TO THE EDITOR:—There is much in the history of the Roman Empire during its long struggle for independence and liberty that resembles the existing state of affairs in our country. For instance: In Rome, 509, B. C., monarchy under the Etruscans ruled supreme. But this state of affairs came suddenly to an end and the monarchical yoke was thrown off by the formation of a republic and a constitutional form of government adopted. In this new republic the people elected as their rulers two consular departments to frame and administer their laws, consisting of the upper and lower houses, in the aggregate comprising 300 members, of which the senatorial department contained 164 electors who were elected for life. These members were chosen from the richest and most aristocratic portion of the people. The assembly or lower house was composed of the medium and lower classes—artisans, tradesmen, farmers and laborers, comprising 125 members; 164 aristocrats of the Senate chamber were from their wealth and influence—all powerful. They had each of them quite an army of retainers and henchmen. They not only claimed, but succeeded in securing nearly all the offices of power, trust and emolument. The votes of the citizens when not cast for the nominees of the aristocratic party were invariably counted out, or at the polls the voter was bulldozed into voting for the nominee selected by their aristocratic rulers.

Political clubs were organized and in operation as at date in this country, the bosses receiving their instructions from their lords and masters as to the manipulation of the ballot box. The petitions of the citizens' masses sent to the senatorial halls for relief were not read, but treated with scorn and contempt, and were either pigeon-holed or thrown into the waste basket.

This state of affairs naturally caused strife and trouble. The lower classes were maltreated, beaten and maimed by the armed retainers of their aristocratic rulers. These retainers, as in our country, represented the police force. The masses were taxed to that extent that they found it extremely difficult to provide food, clothing and shelter for their families. The laws were so stringent that in default of dues the debtor was thrown into prison and his lands escheated to the State or were confiscated by the creditor. The prisons were overcrowded with the so-called pauper laborer, who had no other recourse to earn a livelihood but to enlist as a common soldier in the army, which was officered and controlled by the aristocratic Senators. These plebeian soldiers, while in the wars of conquest which were common at that time, had their families at home, who were poverty-stricken. The soldier on his return from the wars found that his land and home had been confiscated and sold for taxes and dues. This state of affairs continued until 494, B. C. When the poorer classes found themselves reduced to so pitiable a condition, they decided to separate and form a new colony, and at an agreed and given signal they assembled en masse without arms and marched out of the city, establishing their colony and building a new city on the site of the sacred mount, thereby leaving their patrician countrymen masters of the situation in Rome proper to administer to their wants and necessities as best they could. The aristocratic Senators and their henchmen saw that they had gone too far, and they compromised with the people by the appointment of tribunals selected from the masses. The persons composing the tribune were inviolate and held sacred, and their houses were declared houses of refuge both by day and by night. The members of the tribune were granted the right of veto of any and all laws passed by the Senate that were considered injurious to the well-being of the masses. They were, however, not admitted to the senate chambers, but were compelled to remain in the street in front of the senatorial halls, which held their sessions with open doors, the crier proclaiming on the steps such laws as the Senators passed; and if they were found objectionable to the interests of the common-weal, the tribunes shouted in loud voices the single word "veto," which was reported by the crier to the Senators in the senatorial chamber and acted upon. The persons of these magistrates or tribunes of the people were considered as inviolate as the ambassadors of a foreign power.

In fact, the conditions that existed in Rome at that time were not unlike the conditions now existing in our own republic. For instance, if we the people send a petition signed by the majority of our citizens to our representatives in Washington, asking for reform in the administration of our laws, and stating our grievances, the said petition is either pigeon-holed or thrown into the waste basket unread; and if we send a peaceable and unarmed delegation of our people to our capital asking for relief or a modification of our laws, they are not permitted a hearing either in the senatorial halls or on the steps of our capitol, but our delegation is arrested and imprisoned for some fancied and ridiculous violation of the law of trespass relating to accidentally stepping on the sacred grass plat of our capital in

Washington, which is or should be the common property of our whole nation regardless of a few spears of grass that may be trodden upon by some member of our delegation. They are not even permitted to shout the word "veto" as the Romans of old did in the streets and on the steps of their capitol.

JAMES H. CROSSMAN.

545 Baldwin Hotel.

The Cyanide Process in South Australia.

After sundry experimental operations what may be termed the first cleaning-up from the cyanide plant, erected in connection with the Virginia Gold Mining Company's battery, at Wadnamanga, was completed last week, and has been attended with most gratifying results. Mr. J. W. Thistleton returned from the mine last Saturday, bringing with him the yield. From about 400 tons of ore crushed and tailings treated by the cyanide process, the yield of bullion obtained therefrom is represented by four ingots of gold, weighing respectively 37 ozs. 3 dwt., 46 ozs. 12 dwt., and two of 146 ozs. 4 dwt. each, making a total of 376 ozs. 6 dwt., valued at about £1200 for, say, six weeks' work. The smaller ingots represent the quantity (83 ozs. 15 dwt.) saved from the first treatment by the battery, while the two large ingots, weighing 292 ozs. 8 dwt., represent that obtained in the secondary treatment by the filtration of cyanide through the tailings in vats. To the above must be added another 30 ozs., which is the value, proved by assay of the battery's "slimes," that have yet to be treated. As an object lesson of the utility of the cyanide process, the yield under notice speaks for itself. With the ordinary treatment by the battery, as indicated by the gold saved, it would not pay for the working expenses; but with the treatment by the two processes the Virginia mine is enabled to more than pay its way, and employ over 50 miners.—S. A. Register.

Aluminum Alloy.

At the last monthly meeting of engineers in New York some specimens of a new alloy of aluminum and nickel were exhibited which were remarkable. They were sent in by A. E. Hunt of Pittsburg, and both were in the form of rolled sheets a fourth of an inch thick. In one of these a hole about five-eighths of an inch in diameter had been drilled out to about two inches in diameter cold, and the other, which was a strip about three inches wide, 54 inches long, had been bent at the middle, the deflection amounting to about two inches.

It was stated that the force required to do this bending had been about the same as is required to similarly bend a similar piece of 90,000-pound steel, and when the specimen was placed upon the floor and stood upon until straightened it immediately resumed its former shape upon being released; in other words, it seemed to be perfectly elastic within the limits named. The alloy is of a beautiful white color and of remarkably light weight. No information was given as to the proportions of aluminum and nickel in the alloy, but it probably contains only a small percentage of the latter, and so far as could be judged it bids fair to be an important alloy in cases where lightness and strength are especially desired.—American Machinist.

Slickens Land.

Andrew Rapp gave us this week an illustration of the value of slickens. It may be of interest to those whose land has been injured by mining debris, for it shows that in time even the clearest sand changes to loam and becomes fertile. "Garret Keppel," said Mr. Rapp, "owned a large body of land along the line of the Spring Valley Company's canal. On this land was a deep lake, so deep that it was claimed by some to be fathomless. Mr. Keppel turned the water from the canal into this lake and in time filled it up. He afterward planted the land to grain and found that the soil produced marvelously and that it could be plowed at any season of the year.

"Rufus Moore rented a tract of land, and at one time when a change was made in the line of the canal 70 acres covered with slickens three feet deep was left between where the new line was constructed and the old canal had run. He thought nothing would grow on the spot, but at length concluded to test it. He plowed and sowed it and raised upon the slickens 45 bushels of wheat per acre or more to the same area than on any of his other land."—Oroville Register.

Book Notices.

"THE USES OF COMPRESSED AIR" is a handsome brochure of 134 pages, by A. C. Rand of New York. The practical utility of air as a motive power is abundantly demonstrated, and the author, who is a recognized authority on the subject, has made a valuable addition to current literature on this topic. He shows that in all the arts of peace and war where propulsion is required the value of compressed air justifies its consideration. The book is elegantly produced and has nearly 100 original illustrations. It is published by The New York Printing Company. The price is \$1.

Interesting Alaska Letter.

The following interesting letter has been received by the *Deadwood Pioneer* from James Pasco, who is engaged in mining at Forty Mile, Alaska:

"This camp of Forty Mile was discovered last summer, and is the richest yet struck in Alaska, paying \$300 a day to the man. The nature of the Yukon country is such that it is a tolerably hard place to get to. The honorable class of old-time miners have possession, and tough characters, when found, are at once ordered to leave, several having come out recently.

"I will give you prices of a few articles in Forty Mile: Flour, \$14 per 100 pounds; bacon 33 cents per pound; beans, 22 cents, and canned fruits 60 cents. A Mackinaw shirt costs \$8 and a pair of gum boots one ounce of gold-dust. Now comes the root of all evil—whisky. This sells for 50 cents a drink and \$8 a bottle. You can buy everything a miner needs for less than you can take it in for, as the natives will charge 13 cents a pound to carry it over the mountains, a distance of thirty miles, and no one should take anything with him except clothing.

"The town of Forty Mile is at the mouth of Forty Mile

a territorial division has been made, which is said to consist of a line drawn north and south through Europe in a somewhat irregular manner. The Standard, it is said, is to control the trade of the British Islands, France and most of the western portions of Europe, including a part of the German Empire. The Russian companies have gained rapidly for several years in China, India and Japan and are now doing considerable more than one-half of the business of these countries.

Self-Tightening Cam.

Herewith is illustrated the Blanton patent self-tightening cam, manufactured by Fraser & Chalmers of Chicago, E. A. Rix, 104 First St., this city, being the local agent. It is considered an improvement in the construction of stamp mills, being simple in character but effective in purpose.

The cam and its application are shown in the cut. Taper bushings, which may be forged upon the cam shaft, but which are preferably separate pieces secured by pins, afford

BLANTON PATENT SELF-TIGHTENING CAM.

ADJUSTABLE BEVEL BAND-SAW MACHINE.

crusher doing duty at every point in revolution of the pulleys and gears, thus obviating any jar. It is manufactured under the Rutler, Scoville and Fraser patents. E. A. Rix, 104 First St., San Francisco, is the Pacific coast agent.

Adjustable Bevel Band-Saw Machine.

On this page is illustrated an adjustable bevel band saw machine. It is a right-hand machine, designed to avoid the difficulties encountered in holding and guiding work on inclined tables, and can be inclined from 0 to 45 degrees by turning a hand-wheel. When a varying bevel is desired, as for ship work, it can be produced by turning the hand-wheel while the work is being fed to the saw. It is made by P. Prybil, 512 West Forty-first street, New York.

The diameter of wheels is 40 inches. Height of sawing space, 16 inches. Total height, 8 feet 6 inches; width, when set at 45 degrees, 8 feet 9 inches; depth, 4 feet. Loose and tight pulleys, 16 inches diameter for a 6 inch belt. The wheels are covered with rubber, vulcanized upon them. In every case the upper wheel can be angled while in motion, and from the front of the machine. The tension of the saw is maintained by a rubber spring, which is superior to a weight in its ability to yield instantly when a chip gets between saw and wheel, and in not needing separate adjustment when any change of saw is made, as one and the same movement adjusts the upper wheel to length of saw, and produces any degree of tension required.

The Longest Railroad.

The entire length of the Siberian railroad from

THE COMET ROCK BREAKER.

creek on the Yukon. It has two general merchandise stores. One belongs to the Northwest Trading Company and the other to our old-time Montana friend, Capt. John Healy. There are two saloons and one cigar factory here and 150 miners' cabins with about 350 miners. These make up the town of Forty Mile.

"All the northern part of Alaska is more or less level country, and it is difficult to get sufficient grade for sluice-boxes, and in many places they are compelled to use rockers or wheel the dirt to water. Timber is very scarce and in many places they are compelled to haul 40 or 50 miles with dog trains. A dog will draw about 500 pounds on the snow. Game is scarce, except rabbits and grouse. The ground never thaws out in that country, not over five or six feet at most, and they never have been able to dig through it. They work down so far as the frost is out the first year, and then wait for the "never-setting sun" of the next summer to thaw it deeper. The miner can run his sluice boxes but three and a half or four months in the year. The rest of the time he can whipsaw timber for boxes and such sawed stuff as he may require. Some spend the winter trapping furs, but they must be on hand by June 15th or their claims will be jumpable according to the Yukon code of laws."

AS A RESULT of negotiations held in Paris between Standard Oil representatives and those of Russian interests,

seats for the cams, which are bored to fit and work tight upon these bushings. The method advised for securing the bushings is by means of pins as shown, since there is no shearing stress upon the fastening. When necessary to take off a cam, a slight blow on the back edge with a hammer loosens it instantly. For the adjustment of ordinary cams to their proper positions on the shaft they are sent blank, the key seats having to be cut at the mill. The entire cam hub, by its self-tightening construction, takes hold upon the shaft and dependence is not placed on the shearing stress of a key, which is liable to be driven so as to split the cam or impair its strength for severe service.

The Comet Rock Crusher.

The accompanying illustration is of the Comet rock crusher, manufactured by Fraser & Chalmers of Chicago. It is of large receiving capacity and easy motion, and is said to be capable of handling a ton of rock a minute. The axis of the upright spindle is not coincident with main axis of the machine or bevel wheel, but intersects it in the journal at the top, while the lower end is from one-fourth inch to three-fourths inch out of the center, according to the size of the crusher, thus causing a gyratory motion at the bottom of the spindle, the top of the journal being virtually stationary, except the slight motion due to the angularity and which is compensated by the oscillating box, the

Cheliabinsk to Vladivostok is 7112 versts, (4703 miles.) The main line of the Canadian Pacific from Montreal to Vancouver is 2904 miles in length. The estimated cost of the Siberian road is 350,210,482 rubles, or \$269,662,071. This would make the average cost per mile in the neighborhood of \$25,000, which is about the average cost of railroad construction in this country. In the two years during which the Government has been at work good progress has been made. Part of this route presents engineering problems most difficult of solution, for there are mountains to be tunneled or climbed, rivers to be bridged, lakes to be skirted and marshes to be crossed. It is hoped that the entire road will be in operation by 1900.—N. Y. Times.

IN VIEW of the increasing scope of usefulness for compressed air in machine and construction shops, the Clayton Air Compressor Works, Havemeyer building, New York, have issued a special pamphlet of steam and belt actuated air compressors, air governors and air receivers of designs especially adapted to supplying air for this duty. This pamphlet will be sent to those interested upon application.

SMOKELESS POWDER has been followed by a chemical combination called a "fog creator." A German named Reihm is the inventor. It is a shell, which, when it explodes, surrounds in darkness the troops at whom it is aimed. It also causes the soldiers to cough.

Method of the Capillary Electrolytic Sluice in the Extraction of Gold.

PAPER NUMBER TWO.

Written for the MINING AND SCIENTIFIC PRESS by J. H. Jory.

In my former paper on this subject a general outline was given of the character of the process and the conditions on which it is based. On entering into the more specific details of the system, which seems to be warranted by the general expressions of interest evinced, I will reiterate the statement before made; viz., that gold, however placed in nature in the superficial strata of the earth, exists as a metal. Not because this is doubted by scientific men, but because it is generally overlooked by miners in the perplexing difficulties of reducing refractory ores, and that on this fact is based the further proposition that gold may be freed from its enclosing matrix, of whatever chemical character, by mechanical means. For this reason of its natural condition, the rock containing gold is not usually spoken of as "ore" by metallurgists, although the term is sometimes used as a matter of convenience and in its relation to the other mineral compounds contained therein.

The problem of the extraction of gold, therefore, is in reality a simple one, notwithstanding the conditions involved in the simple process of saving the metal reduced to its ultimate subdivision and floating in sluices have appeared so insuperable that metallurgists have preferred to take the bull by the horns in attempting to recover the precious metal by reducing not only the gold, but the various chemical compounds contained in the matrix, which is a very complex problem indeed.

The capillary electrolytic sluice assumes the possibility of the solution of the simpler problem, and accomplishes that result in the manner briefly described in the former paper.

The apparatus is formed of about 50 amalgamated copper plates arranged almost vertically in a box-like sluice, each plate being hung on four pivots in such a manner that simultaneous movement may be communicated to the series by an adjusting screw placed at one end of the sluice-box, opening or closing the spaces between the plates in a manner similar to the movement of the slats of a Venetian blind. These plates are 12x14 inches in dimensions, and one-quarter inch thick; the spaces between, which are termed capillary passages, are, when the plates assume a vertical position, about two inches in width, but when adjusted to receive the fluid in which the gold is held in suspension, the plates recline at about an angle of 45 degrees, and the capillary passages approximate to about one-fiftieth of an inch, a floodgate at each end of the sluice preventing the passage of fluids except through these passages.

The electric current produced by a one to three-horse power dynamo is conducted by wires attached one to each of the end plates of the series; the series being brought into circuit through the medium of the fluid between the plates. In practice, the pulp from the battery, properly diluted, flows into the sluice-box until it attains a depth of about one foot, when, if the plates are properly adjusted, the weight of the superimposed fluid will be sufficient to cause a discharge through the capillary passages equal to the influx; the greater depth of the fluid causing a greater discharge, and vice versa, thus securing an equilibrium in this regard, within certain limits, automatically. The occasional readjustment necessary, consequent on the coating of the plates by the precious metals, is made by a simple turn of the adjusting screw. The water supplied to the battery should be about one-third more than is usual; this is especially necessary when the rock is magnesian or aluminous in character, to secure a proper discharge. To obtain the necessary pulverization, the screens on the battery should be fine, those made of brass wire with a mesh of 100 to the linear inch being most suitable for this process.

There are two advantages secured by the arrangement of the plates described above, aside from its electrolytic possibilities. In the first place, the stream is divided into numerous narrow channels through which it is impossible to pass without bringing the metal held in suspension into intimate contact with the amalgamated plates. Second, the peculiar molecular force induced by the proximity of the plates greatly increases their attraction for those metals with which they are in affinity, by what is called capillary action, thus rendering it still more improbable that any metal such as gold, silver or mercury should pass the proximate amalgamated surfaces without adhering thereto. But by considering how infinitely both these probabilities of contact and adhesion are increased by the electric current employed, by its electrolysis in decomposing the films of oxides or sulphides, clouding the amalgam or the particles of gold, and its electro-motive power in carrying and adhering those particles, it will be seen how improbable, theoretically, is the escape of any of the precious metals

contained in the flow; and in this case the fact is very conformable to the theory.

The effect of a continuous current of electricity when employed in this apparatus is to attach such positive elements as the metals named above to the negative surface of the plates in circuit, and to attach some of the negative elements contained in the matrix to the positive surface, though in a much less permanent manner, yet tending to clog the capillary passages. For this and other reasons an alternating current is employed which has the effect of adhering the gold to both surfaces and causing a perfect discharge of the elements not desired.

The sluice described above is adapted to the service of a five-stamp battery, and being of a convenient size it is better to employ a number of sluices in large mills, or in hydraulic mines, rather than to increase its size, although this may be done if found more convenient. Sluices of a much smaller capacity may also be made, electrically supplied by chemical batteries, which may be used in the laboratory or in the assaying department of mills as detectors of waste in the outflow and for other purposes; an exact determination of the weight of the plates before and after a few hours run giving a very simple and practical test.

There are other forms of the capillary electrolytic sluice of more complex designs than this that has been described, which is adapted to metallurgical processes of a more complicated character; but as these do not come within the scope of the present paper their description must be left to some future period.

Gold Placers Formed by the Wind.

In the early days of gold mining in California, deposits of sand and gravel rich in the precious yellow metal were occasionally stumbled upon in strange and unexpected places. They were generally formed by the action of water at some period in the past ages, though there were those that were the result of slides. However, as the paying gravel in the slides came from deposits formed by ancient rivers and water courses, it may be said that water was the active agent in the formation of all the old California placers, both great and small. Now that mining is being pushed far out in the almost waterless desert regions, we are finding some new puzzles. One of these, says the *Enterprise*, is seen in the rich dry diggings of Summit district, on the Mojave desert.

"In this new district are over 200 permanent settlers, and already some 60 dry-washing machines are constantly at work. The "dry washers" are winnowing machines through which the dry soil and sand—the pay dirt—is run as grain is run through a fanning mill. All these machines are paying well. Reports from the district say: "Curiously enough, the flat mesa lands pay better than the gulches, and the ground yields more gold right at the surface than it does deeper down."

This at first sight seems very singular, and it is quite contrary to anything ever seen in the old gold placers of California, those in and bordering upon the Sierra Nevada mountains. The explanation of the mystery is, however, doubtless to be found in the action of the heavy winds which sweep over the desert. The sweeping gales blow away the sand and the light, decomposed soil, leaving the gold behind. In the rainy season all the gulches become torrents, and soil and sand, containing gold, are swept down and deposited upon the flats. As soon as the rains are over the wind catches up and carries all the light material, leaving on the flats the grains of gold. Indeed, we see that nature has here set up a big winnowing or dry-washing machine of her own, and by means of it has formed a gold placer of a novel kind. In the waterless Mojave region the desert winds perform the work that was done by water when the placers of the Sierra Nevada range were formed.

The Price Suit.

The action commenced by the Bank of California against Thomas Price in the matter of the disposition of certain real estate in this city is a friendly suit intended to straighten out some financial matters between the parties involved. The firm, which still commands one of the largest businesses of the kind on the coast, got snarled up some time ago owing to its heavy investments in ditch property of considerable value in Placer and Nevada counties. Over \$200,000 is tied up temporarily in the El Dorado Water Company and other contingent interests, which when cleared up will eventually put this old, respected firm on its feet again, financially as strong as ever.—Evening Post, May 16th.

The steamer *Britannic* has recently completed her 200th round voyage and 400th passage across the Atlantic. She has traveled a distance of nearly 1,500,000 statute miles with her original engines and boilers.

Native Miners in Mexico.

In Mexico, says J. H. Palmer in the London *Mining Journal*, miners form a caste apart, and a very aristocratic caste, too—looking down upon rancheros and agriculturists generally with fine contempt. After all, they have good reasons for thinking themselves superior to the cultivators of the plains. A miner is easily worth his \$1 a day, besides being very much his own master, whereas the best agricultural laborers do not earn more than 25 cents, if so much, per diem, and through debt and ignorance they are still in a condition not far removed from slavery. The miners, on the contrary, are very independent, and a foreigner has to exercise considerable tact if he means to get on with them. The Mexicans are very proud and sensitive in many ways, and an angry word or an ill-judged rebuke is often quite enough to make a good man leave his work; on the other hand, with those who can combine kindness with authority, they are the best of workmen, steady, courteous and intelligent.

There are three classes of labor employed underground in Mexico—miners proper, *fáneros*, or unskilled laborers, whose business it is to clear out the workings after a blast, and *tenateros*, or packers, who carry the roughly sorted ore and waste to the shaft or adit tramway. The skilled miners work in gangs of eight men each, and are paid by contract. Each gang has a captain, who alone is responsible to the engineer of the mine. These contractors have to buy their dynamite, candles, etc., from the mine stores, but are provided with drills, which are weighed at intervals and the wear charged against the gang. A drift 2 meters by 2 will cost about \$20 to \$40 per meter, but the contractors are not expected to remove the broken rock. This is done by the *fáneros*, who work on day wages of 50 to 75 cents. These men also sort the ore roughly, clean out the workings and put the stone ready for the *tenateros*, who sack it up and carry it to the shaft. These *tenateros* are paid so much per sack, according to the weight and distance traversed. They can carry as much as 150 pounds at a time up the steepest winzes, and earn from 75 cents to \$1 per day. The work is very severe and exhausting, and heart disease and lung trouble are only too rife among them. Ore shoots and tramways in the levels are not used to the extent they should be, and though there is never any difficulty in getting sufficient ore broken down, want of labor often causes much vexatious delay in bringing it to the surface.

A cheaper way of working than the foregoing is to let a mine out in sections to *buscones* or tributors. Each party has so many feet along the vein or an end to drive. They pay all their expenses and are entitled to half the ore they bring out. The mine generally buys the *buscones'* half at a fixed price on the assay value, but they are sometimes allowed to take their ore away on their backs for sale elsewhere. Letting out a mine to *buscones* is advantageous in the early stages of development, for the Mexicans will make a good living out of a poor vein, where a company cannot even expect to make expenses. In this way a mine can be opened up very cheaply, but these tributors require very careful watching in order to restrain their "burrowing" propensities; as their reward depends entirely upon the ore they bring out, they are not very anxious to do any dead work, or to remove a single stone more than they can help. If they are not properly looked after the result, of course, is a network of narrow, tortuous and dangerous workings, which have to be widened and squared off afterwards at the expense of the mine. *Buscones* are also employed in those parts of a mine that are nearly worked out, and where it would not pay to set an ordinary contract. They know the ore so well, and are so acute and persevering in following up the narrowest stringers, that they can keep workings in operation long after they would otherwise have to be abandoned, and thus often pave the way for future discoveries.

When the ore reaches the surface a great deal is done to it before it is considered to be ready for the reduction process. In all the dry ores the silver-bearing minerals are so finely disseminated throughout the gangue that any system of mechanical concentration is quite out of the question. In Colorado and Montana, where labor is dear, and fuel and crushing power are cheap, all the lode matter goes straight from the mine to the mill without any preliminary sorting, but in Mexico, where cheap skilled labor is abundant and machinery expensive, it does not pay to crush large quantities of waste rock, and hence an elaborate and efficient system of hand picking and sorting is in vogue. Any large lumps of ore are broken up, and the rest is thrown upon an inclined grizzly, with $\frac{1}{4}$ -inch mesh to remove the fine stuff or *tierras*. All that will not pass the grizzly is then washed upon a sloping stone table or *lavadero*, provided with a tank at the lower edge. This tank is cleaned out from time to time, and the mud collected will often average 40 ounces of silver per ton. The washed ore is then handed over to the sorters or *pepena-*

dores, who chip off the worthless portions, and classify the mineral into grades either for shipment or local treatment. All ore containing over 200 ounces of silver per ton is generally sold to the agents of American smelting companies, anything of lower assay value going to the patios. In Guanajuato and Zacatecas the average product of the mines at present is from 20 to 30 ounces of silver, with a varying amount of gold per ton, and it is found that the patio process works best upon ores of this richness. The waste rejected by the sorters should not contain more than six or seven ounces of silver, and this is again picked over upon the dump, so that very little is finally lost. The cost of all this sorting is about \$1.50 per ton, but considering that the low assay value of the ore is generally doubled, and that the waste goes to the dump instead of being crushed, it seems that there is ample justification for this expenditure. In many mines without reduction works the sorted ore is sold by assay as it lies at the mine, and is packed off on mule-back to the towns for reduction. In the older districts there are plenty of reduction establishments which are glad enough to buy ore at very fair prices, so that a new enterprise is not under the necessity of buying expensive crushing and amalgamating machinery until the mine is properly proved.

Electric Mine Locomotive.

Concrete examples of the adoption of electricity to the exclusion of all older methods are generally more convincing in their import to the public mind than mere hearsay or description. The illustration shows a striking example of the supersession of older haulage methods by the electric mine locomotive in an important coal mine in Pennsylvania, and emphasizes the vast advantage which its use confers.

The mine in question is the Bear Run mine of the Blossburg Coal Co., near Landrus, Tioga county. The locomotives, of which there are two, are of the T. M. M.—that is, "two-motor-mining" type, each of 30-horse power, manu-

run into places impossible to any mule, and their ease of control and operation is such as to render them invaluable.

A Boon to Merchants and Shippers.

The cut presented herewith tells its own story. This fountain marking brush is clean, handy and always ready for use. It will pay for itself many times over as a convenience and time-saver. It is the invention of R. G.

BAILEY'S FOUNTAIN MARKING BRUSH.

Bailey of San Francisco, and will doubtless come into general use on its merits.

The tube is charged by unscrewing the cap from the top and filling with any ordinary clean marking ink, such as lamp black and turpentine. One filling will do a great amount of marking. To use, open the valve by

ELECTRIC MINE LOCOMOTIVE.

factured by the General Electric Co. They are propelled by two W. P. 30 motors, one being geared to each axle. Current is brought to the motors by a specially designed trolley arm, on which the trolley wheel is swivelled, to permit of its adjustment to the various irregularities of the wire line. The trolley arm can be set in sockets on either side of the locomotive, which may thus be run into headings on either side of the main haulage way which is lighted by incandescent lamps placed at the entrance to each cross-head, 100 yards apart. The dimensions of the machines are: Horse-power, 30; speed, 6 miles per hour; draw-bar pull, 1500 pounds; gauge, 36 inches; wheel base, 30 inches; diameter of wheels, 28 inches; width over all, 48 inches; length over all, 9 feet 6 inches; height above rail, 31 inches; weight, 7500 pounds.

The current is furnished by a General Electric D 62, 75-horse power generator, driven by a Harrisburg Ideal 30-horse power engine.

The maximum load which these locomotives have been called upon to handle is 32 loaded mine wagons, each weighing 3200 pounds, and the way is one part a 3 per cent grade. The daily haul of the locomotives is about 650 tons.

The entire plant has been pronounced eminently satisfactory, the locomotive having shown capabilities beyond the specification or the General Company's guarantee. Their presence in the mine has done away with the slow-going, limited mule, and induced great economy. The small height of the machines above the rail level allows them to

unscrewing the tube at the bottom about one-fourth of a turn, or till the ink flows over the brush. Two or three trials will enable any one to control the feed perfectly. When not in use, the valve is to be closed.

The brush can be replaced when worn by any common brush of same size as easily as placing a new pen in a pen-holder.

Deep-Sea Soundings.

A ship regularly engaged in deep-sea sounding has the sounding machine mounted in the after-end, and when about to sound is brought to a standstill, with the stern to the sea. The stray line, with the sounding rod attached, is over the guide pulley and carefully lowered to the water's edge, the register is set at zero and the deep-sea thermometer is then clamped to the sounding line; a seaman is stationed at the friction line, which controls the velocity with which the wire is unreeled, another at the brake and a third on the grating outside to handle the sinker and instruments and to guide the wire as it passes overboard; a machinist is at the hoisting engine and the recorder takes a position for reading the register. When the sinker is let go the vessel is maneuvered so as to keep the wire vertical, and the friction line is adjusted so as to allow it to descend from 70 to 100 fathoms per minute.

The instant the sinker strikes the bottom, which is unmistakably indicated by the release of the wire from strain, the reel is stopped by the friction line and brake; the recorder notes the number of turns of the reel. In an hour

this messenger of man's ingenuity makes its excursion through five miles of watery waste to the abysmal region of perfect repose and brings to the light of day the soil with which the rain of shells of minute infusorial organism from the upper waters has been for ages mantling the ocean's floor. Here and there a giant peak rising from these sunless depths lifts its head to see the sky and the dredge and trawl tell us that along his rugged sides, and on the hills and plains below, and even in the inky blackness and freezing cold of the deeper valleys there is life.—Popular Science Monthly.

Minerals of the Pacific Northwest.

TO THE EDITOR:—Herewith find a list of minerals of economic value, and their locations, found in the Pacific Northwest, of probably sufficient value to warrant publishing. It will certainly be of great interest to your large circle of readers in Oregon, Washington and Idaho, and, probably, elsewhere. READER.

ANGLESITE (Sulphate of Lead)—Surface ore of many argentiferous lead mines; Wood river, Coeur d'Alene, Colville in fine crystals. ARGENTITE (Silver Sulphide)—Silver City; Taboma mine, Atlanta; and elsewhere.

ARSENOPYRITE (Arsenical Iron)—Applegate, Oregon; Rocky Bar, Granite, Yuba, Idaho; and elsewhere.

AZURITE (Blue Carbonate of Copper)—Lemhi, Custer and Alturas counties, Idaho.

BARITE (Heavy Spar)—Yank vein, Josephine county, Oregon; Mulan, Shoshone county, Idaho.

CALCITE (Limestone)—Polk county, Clackamas county, Rogue river crossing, Jackson county, Williams creek, Josephine county, Oregon; Shoshone county, Alturas county, Idaho.

CEMENT (Natural Cement)—Oakland, Douglas county, Oregon. CERARGYRITE (Chloride of Silver)—Owyhee mines, and other parts of Idaho.

CERUSSITE (Carbonate of Lead)—Wood river, Coeur d'Alene, Colville, and elsewhere.

CERVANTITE (Antimony Ochre)—Wood river mines, Mountain City, Bitter Root mountains, Idaho.

CHALCOPYRITE (Copper Pyrites)—Cow creek, Douglas county, Oregon; and in many gold mines.

CINNABAR—Evans creek, Jackson county, Oregon.

CUBANITE (Copper Ore)—Near Kerbyville, Josephine county, Oregon.

CUPRITE (Oxide of Copper)—Rogue river, Oregon.

DUFRENOYSITE (Sulpharsenide of Lead)—Crown Point mine, Banner district, Idaho.

FEIBERGITE (Silver-Bearing Gray Copper)—Sawtooth district; Coeur d'Alene mines, Idaho.

GALENITE (Galena)—Santiam mines; Near Table Rock, Clackamas county, Oregon; Wood river, Lemhi, Coeur d'Alene, Idaho; Colville mines, Pend d'Oreille district, Washington.

GARNIERITE—See Nickel Ore.

GOLD (Native)—Pebastin and Swauk districts, Washington. Numerous placers and veins in southern and eastern Oregon. Placers of Boise basin, Snake river and other old alluvial washings. Quartz gold at Yankee fork, Mt. Estes, Rocky Bar, Atlanta, Red Warrior, Canyon Creek, Linn City, Murray, and other districts. Fine specimens of crystallized gold from Gold Hill mine, Boise, Idaho, and White Bull mine, Santiam district, Oregon.

GRANITE—Principal country rock of central Idaho; excellent building stone, but not used. Some apparently double granites are found in the upper Yakima region. Abundant in Pine creek, Union, Baker and Jackson counties, Oregon.

GRAPHITE (Black Lead, Plumbago)—Siskiyou mountains, Jackson county, Oregon.

GYPSUM (Plaster of Paris)—Union county, Oregon.

HALITE (Rock Salt)—Southern Idaho.

HEMATITE (Iron Ore)—Wood river (Chase's mine), used as flux. Near Caldwell (Nargansett mine); Lake Pend d'Oreille, used as flux; Cle-el-lum district, Washington.

IRIDOSMINE—In gold placers, southern Oregon.

JET—Clatsop county, Oregon.

LIGNITE (Coal; Brown Coal)—King and Pierce counties; Whatcom, Skagit and Lewis counties, and numerous other localities near Puget sound, Cowlitz river, Washington; Coos bay, Tillamook, Clatsop and Columbia counties, Oregon; Lookingglass prairie, Douglas county, Oregon; Goldendale, Washington; Crooked river, Oregon; Salmon river, Idaho; Owyhee, Ada and Boise counties, Idaho.

LIMONITE (Brown Hematite; Bog Iron Ore)—Oswego, Clackamas county; Multnomah, Marion and Columbia counties in large deposits—in Oregon. Jefferson county and other localities in Washington.

MAGNETITE (Magnetic Oxide of Iron)—Gold Hill, Jackson county, Oregon. Ocean beaches of Oregon and Washington; McKenzie river, near Eugene; Snake river placers; many mines in Idaho and Washington.

MALACHITE (Green Carbonate of Copper)—Big Lost river, Lemhi county, Idaho.

MARCASITE (White Iron Pyrites)—In some gold mines.

MUSCOVITE (Mica; Isinglass)—Near Spokane Falls, in large sheets; a valuable source.

NICKEL ORE—Big Pine mountain, Douglas county; also, Baker county, Oregon.

OCHRE (Red and Yellow)—Oregon City.

OSMIRIDIUM—See Iridosmine.

PLASTIC CLAY—Near Tacoma, Washington.

PROUSTITE (Light Ruby Silver Ore; Arsenical Ruby)—Monarch and Buffalo mines, Atlanta, Washington. Sawtooth district, and other localities.

PYRRARGYRITE (Dark Ruby Silver; Antimonial Silver)—Atlanta district, Sawtooth district, Smiley's basin and Owyhee district, Washington. Monumental mine, Grant county, Oregon.

PYRITE (Iron Pyrites)—In most gold mines. In concretions and masses, Yamhill county, Oregon.

PYROLUSITE (Manganese Ore)—Columbia county, Oregon; Shaw's mountain, Washington.

PUMICE—Cascade range and eastern Oregon; southern Idaho.

SANDSTONE—Fine varieties, including freestone, near Boise City; Coast range, and Cole's valley, Douglas county, Oregon; a fire-resisting material, suitable for furnaces, hearths, etc.

SILVER (Native)—Atlanta district. Owyhee, Eagle City, Shoshone county, Idaho, in quartzite; and many other localities.

SPHALERITE (Zinc Blende; Black Jack)—Bonaparte mine, Atlanta, Wardner district. Santiam mines (auriferous), and generally accompanying galenite, pyrite, etc., in mineral veins. Heavy masses in Bohemia district, Oregon.

STEPHANITE (Brittle Silver)—Custer mine, Yankee fork; Queen's river district, and elsewhere.

STIBNITE (Sulphide of Antimony)—Mountain City, near Murray, Idaho, in very large deposits, said to be argentiferous. Wood river mines, Idaho. Santiam and Bohemia mines, Oregon.

TETRAHEDRITE (Silver Fahlore; Gray Copper)—Shoshone county, Idaho, and elsewhere. A very obscure and uncertain mineral. Most of the so-called gray copper is zinkenite, a sulphide of lead and antimony.

ULENITE (Borate of Lime)—Curry county, Oregon.

Scientific Progress.

New Chemical Methods.

It is noticeable, although not remarkable, that important or interesting discoveries should so often be made simultaneously in different places. It is not remarkable, because contemporaries work in the same field and with practically the same capital produced by the collected experience of their predecessors. The mechanical production of diamonds is an example of this. Henri Moissans had scarcely published the results of his beautiful experiments, when three other French chemists stated that they had been occupied with the same problems, and each with more or less success, as having produced crystals of varying degrees of hardness.

But to leave diamonds and all their connections and take a look at gold. And first of all we must put entirely aside any question as to whether gold can be artificially produced. Carbon is found in three states, the most important of which is the form of the diamond; but gold exists only as a yellow, heavy and soft metal, which we know, and which we can obtain only by separating it from its union with tellurium, silver, copper, or from stones in which it is concealed, the so-called veins.

A weak solution of cyanide of potassium in water dissolves gold; very slowly when in a solid state, but very easily as a powder. This capability of solution exists so far that a crystal of coppery sand containing gold retains its exterior form in this solution after a sufficient length of time has elapsed; when under the microscope it is observed that it seems to be interwoven with layers similar to those of the honeycomb. These show the positions in which the dissolved gold had settled in the fine cracks of the crystal. On this circumstance, which has been known for 50 years past, MacArthur and Forrest founded their experiments of extracting gold from unburnt clay. Practically, however, this experiment does not run so smoothly, and besides, it is very expensive. In the first place, a great deal more of the solution was needed than the theory demanded, viz., that two parts of this salt would suffice to obtain three parts of gold. Further, this method could not be used for rich earths, because the thick grains of gold found therein would not completely dissolve, and such earths as contain other metals beside gold, which must also be obtained by this solution, which, as in the former case, becomes too expensive. On the other hand, it is a most excellent method for obtaining that gold which is scattered in such fine particles that the single little gleams thereof, freed from the vein by pounding, remain on the surface of water for several hours, although 19 times as heavy.

Working with cyanide of potassium is never pleasant, although not so dangerous as might be feared, considering the great number of men employed in it. It causes very painful ulcers in any sort of wounds, and the workmen complain greatly of headache, faintness and dizziness. If a quantity of sulphuric acid were poured into one of the enormous casks containing the pounded earths and cyanide of potassium, so that the Prussian blue would be driven out into a closed room, scarcely one life out of a hundred could be saved, as the Prussian blue paralyzes the nervous system with the rapidity of lightning. This operation has had to struggle painfully for a place, as the gold-diggers look upon it with the greatest suspicion. But it is already considered indispensable as a means of obtaining the "floating gold" above mentioned, and for the further profits of the earths from which the principal parts of the gold have already been obtained. In the Transvaal, a sixth part of the total production is obtained by means of this method, and it is to be hoped that earths which have formerly been useless may also

be worked out by it.—Translated from the Berlin Tageblatt.

Aluminum Headlight.

A headlight is now manufactured which will be highly appreciated by medical practitioners. Since the practice of transillumination, or the lighting up of animal tissue in order to detect morbid growths, has been introduced into surgery, great improvements have been made in means whereby the surgeon can instantly project a flood of light on any desired surface by a powerful lamp, attached to a band encircling the head of the operator. The improved lamp is of aluminum, and is so light that its weight is scarcely perceptible on the head. A universal joint enables the light to be changed to any required position. The front of the lamp has a disk of glass, in the center of which is a lens which throws a strong and concentrated light on the point of operation. The edges of the disk are ground glass, so that a diffused light is shed upon the surface immediately surrounding the point most brilliantly illuminated, instead of its being in total darkness.

Smokeless Powder.

Some interesting results with a new brand of smokeless powder discovered by a Virginian have just been reached with the four-pound rapid-fire gun at the Washington naval proving station. This powder was developed by a Mr. Leonard, and experiments with it prove that it is the superior of any yet discovered, either abroad or in this country, and that it is probable that the Navy has at last found a brand that will answer all requirements, both for the new small arm and heavier ordnance.

The new powder is manufactured in solid bricks 24 inches in length by 12 inches in diameter. Eleven pounds of powder gave a velocity of 2537 feet and a pressure of 28,000 pounds, and the highest charge (12 pounds) used gave a velocity of 2736 feet and a pressure of 17.8 tons. These velocities are the highest ever obtained in this country. The results are considered by ordnance officials to be of the highest importance, inasmuch as they place the powder at the head of any yet made.

Progress in Melting Iron.

The introduction of some late inventions for melting iron indicates the march of progress in this particular very forcibly. Every effort is now put forth to prevent the immense waste of heat which occurs in ordinary cupola melting, by a disposition of the tuyeres such as will burn the ascending combustible gases without heating the fuel to incandescence, in which instance the developed heat preheats the iron and fuel before it reaches the melting zone. What may we not expect in the prevention of heat waste when we find that electricity has at last been successfully applied for melting cast iron? It is claimed for the "Taussig" electric system of melting cast iron in exhausted chambers that oxidation and creation of air bubbles are avoided, and the cost for driving the dynamo is 50 per cent less than would ordinarily be required for melting by the best practice. — Eng. Magazine.

Detecting Dynamiters.

Chemistry is offering a means to oblige would-be dynamiters to betray themselves should they try to carry about hand grenades and cartridges. It is to mix dynamite with certain salts that give out a stench, and plunge cartridges into a solution of these chemicals. This fetid smell thus caused is not to be got rid of, and is communicable. A person carrying this infernal machine, or who had carried or handled one, unless with leather gloves which had been taken off with great care, would be at once detected by the odor.

A CINCINNATI MAN has invented a traction gasoline engine, the first in the history of the world. It can be run cheaply at high speed without danger, and will, it is predicted, displace the trolley.

THE latest theory of the origin of the canals of Mars is, that they are the result of smaller bodies striking the planet at a tangent. This would account for the perfect straightness of the canals.

A BILL was passed at the last session of the New York State Legislature offering a prize of \$50,000 for the invention of an economical street-railway system of traction.

SINCE M. Pasteur began to practice his inoculations against hydrophobia 14,430 persons have been treated by his method, of whom only 72 have died of the disease.

Metallurgy and Ores.

SELBY SMELTING AND LEAD CO.

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

— AND — ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

— MANUFACTURERS OF —

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

— ALSO MANUFACTURERS OF —

Standard Shot - Gun Cartridges, Under Chamberlain Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balance, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

J. F. CROSETT, Commission Mining Agency,

628 Sacramento St., San Francisco, Cal.

Buy and Sell Meritorious Mining Properties. I have orders for Income-Paying Mines at the present time. Have also some good properties for sale. I want more mines to offer to purchasers and also desire more purchasers to examine properties I have to offer. Correspondence solicited.

Mechanical Progress.

Natural Gas Production.

THE only State in which the use of natural gas for manufacturing purposes increased last year is Indiana. The total value of natural gas consumed in the country in the year was \$14,346,250, against \$14,800,714 in 1892. The higher prices charged for the gas in 1893 was the cause of the decrease. The greatest value of the gas consumed in any one year was \$22,629,875 in 1888. Since that time there has been a gradual decline, with an aggregate of about \$8,300,000 less for last year than 1888. All States show a falling off in the value of coal or wood displaced by the use of gas. The amount of this reduction in Pennsylvania was \$420,000; in Ohio, \$48,000; in Indiana, about \$1300. The largest value in any one year of the gas produced was \$19,282,375 in 1888, in Pennsylvania, since which it has fallen to \$6,488,000. Ohio showed the largest falling off for the year 1893; in 1892 the value was \$2,136,000; in 1893 it was \$1,510,000. The most important gas field in any State is shown to be in Indiana, the estimated productive gas territory in which is about 2500 square miles. While the supply is falling below the demand in other gas fields, it is declared to be well sustained in Indiana, and supplies are being obtained from the State by factories located in other gas territories. The value of the product consumed in the State in 1893 was \$5,718,000, against \$4,716,000 in 1892.

The value of natural gas consumed in California in '89 was \$12,680; in '90, \$33,000; in '91, \$30,000; in '92, \$55,000; in '93, \$62,000.

French Hydraulic Forging Press.

A French journal describes a forging press of very large size, on the Breuer-Schumacher system, which has recently been built by Delatre & Co., at Ferriere-la-Grande, for the Couillet forges in Belgium, and which develops a force of from 1800 to 2000 tons. The press on this system is composed essentially of two parts—the press itself and the compressor. The compressor is formed of a vertical steam cylinder and a hydraulic cylinder, the latter of forged steel. The piston rod of the steam cylinder forms the piston of the hydraulic cylinder, the latter being connected to the steam cylinder and to the foundation by four columns of forged steel, and by hollow cast iron columns surrounding the steel rods, and forming the connection between the head of the steam cylinder and the upper cover. The hydraulic piston discharges the water into the press proper. The distribution is made by a cylindrical balanced valve; as soon as the pressure is released the steam piston falls automatically under the action of gravity. The press at the Couillet forges is remarkable, not only for its huge proportions, but also for its rapidity of action, a speed of 30 blows per minute having been maintained. It is not, however, the largest of the kind yet constructed, since a double press on the same system, having two compressors and giving a maximum pressure of 1000 tons, has just been erected in the Krupp works, at Essen, where it will be used on armor plates.

Building Stone Report.

A report on the valuation of building stone produced in the United States during 1893 has been completed by the special agent of the United States Geological Survey, and shows an aggregate valuation of almost \$22,000,000, a decrease of over \$15,000,000 from that of 1892. "Slate produced during the year was valued at \$2,523,173, of which \$1,472,275 is credited to Pennsylvania. The product of Vermont was valued at \$653,572, and of New York \$204,982. The valuation

of the product of other States is given as follows: Georgia, \$11,250; Maine, \$139,200; Maryland, \$37,884; New Jersey, \$3,653; Utah, \$850, and Virginia, \$117,347. The sandstone production had a valuation of \$5,195,151. Of this amount \$2,101,932 was from Ohio and \$622,552 from Pennsylvania. Limestone production was valued at \$13,920,223. The States having the largest production were Illinois, \$2,305,000; Ohio, \$1,848,063; Indiana, \$1,474,695; Maine, \$1,175,000; Pennsylvania, \$1,552,336, and New York, \$1,103,529."

Battle-Ships Ready.

An official report of the instantly available battle-ships of the six great powers shows that of first-class vessels England has 15, France 9, Russia 3, and the Triple Alliance 10, of which 9 are Italian and 1 German. All the English vessels steam 16½ knots and upward, two being 18½; none of the French is over 16.2, while two of the three Russian are under 16, the third reaching 17.8. In second-class ships England leads with 12, France has 9, Russia 4, and the Triple Alliance 11, of which Germany owns 7 and Austria 4. Here there is no such superiority of speed on the English side, three being under 13 knots, while no French vessel goes so low as that figure and all the Russian steam 14 knots and over.

The Conning Tower of an Ironclad.

The conning tower of a modern ironclad warship is only a bombproof pilot-house whence the ship may be steered in time of action, and is not primarily a safe post where there may be kept an outlook upon the enemy. Conning is a very old word for directing the act of steering a ship. It comes from the ancient word "con," to know, to watch, and the conning tower really comes pretty close to a conning tower, though there may be a certain touch of the whimsical in the idea.—New York Sun.

ONE of the annoyances of several of the most deservedly popular of the type-writing machines is the fact that the carriage has frequently to be lifted, that the operator may examine the work as it progresses. The necessity for this is obviated by a simple device recently introduced and styled the "Typewriter Prism," a rod of polished cut glass fastened to the carriage beneath the impression roller. Two of its slides are flat and inclined to each other at an angle of 45 degrees, and the third side is a strong cylindrical curve, perfectly reflecting the writing and presenting it right side up and in normal position to the eye of the operator.—Scientific American.

THE greatest hoisting engine probably ever built is now being constructed in Milwaukee. It will operate a shaft on the property of the Tamarack (copper) Mining Company in upper Michigan. This shaft is 9400 feet deep, and the engine will be large enough to hoist from a depth of 6000 feet. The drum will consist of a double cone, with the greatest diameter at the center, and tapering toward each end, the smallest diameter being 13 feet 9 inches, the greatest diameter 36 feet, and distance across the face of both cones 24½ feet.

It is claimed that aluminum will soon replace tin for all household purposes. A process for plating aluminum has been devised by a German chemist, which increases its chances of becoming universally popular in household economy.

THE new rifle adopted by the Government is called the Craig-Jorgenson rifle. The Infantry will be furnished first, and, as soon as possible, the cavalry will be supplied with the same arm. It weighs only eight pounds, and will kill a man at the distance of two miles. It is a breech-loader, and has a magazine that will carry five cartridges.

The ball has a speed of 2000 feet per second, and with smokeless powder, with which it will be charged, it is claimed that the bullet will kill a man before the sound of the discharge reaches him.

TALKING of flying machines, *Cosmos*, an English paper, states that "the apparatus of Mr. Lilienthal enables a man to fly without the use of any power but that of the wind. He has successfully flown down from the top of a bill, and has during his flight even risen higher than the starting point, using the wind for power. The machine consists simply of a pair of large fixed wings and a large tail, there being apparently no power used but that of the wind and the balancing of the body."

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 60-horsepower engine and 45-horsepower boiler, with Ore-crusher and other machinery, Mill Scales, Assaying outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

EASTERN PRICES BEATEN.

San Francisco Pioneer Screen Works

JOHN W. QUIOK, Proprietor.

IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.

Perforated Sheet Metals, Steel, Russia Iron, American Planish, Zinc, Copper and Brass Screens for all uses.

MINING SCREENS A SPECIALTY.
221 & 223 First St., San Francisco.

UNION IRON WORKS,
SACRAMENTO.....CALIFORNIA.

ROOT, NEILSON & CO.

—MANUFACTURERS OF—

STEAM ENGINES, BOILERS

And all kinds of

MACHINERY FOR MINING PURPOSES.

FLOURING MILLS, SAW MILLS AND QUARTZ MILLS.

Machinery constructed, fitted up and repaired.

Front St., bet. N and O, Sacramento, Cal.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, White Line, etc., etc.

Extra sizes and lengths made to order on short notice.

611 & 613 Front St., San Francisco, Cal.

GOLD EXTRACTION EXTRAORDINARY!

Two Improved Crawford Mills have treated about one thousand tons ore at the Columbia Mins, Moors County, N. C., capacity of each mill being over 10 tons daily, and the cost of wear and tear 20 cents per ton. On a formal trial run of 100 tons, 84 per cent of ore's value was cleaned up in gold, exclusive of some rich concentrates produced by mill. Thresh additional Crawford Mills have been added to plant at this mine.

CHEAPEST AND BEST MILL IN THE MARKET.

MECHANICAL GOLD EXTRACTOR CO., 47 Broadway, New York.

W. O. ROSS, Sec'y and Treas.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE OUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

Founded by Mathew Carey, 1785.

HENRY CAREY BAIRD & CO.,
Industrial Publishers, Bookellers and Importers,

810 Walnut St., Philadelphia, Pa., U. S. A.

Our new and Revised Catalogue of Practical and Scientific Books, 88 pages, 8vo., and our other Catalogues and Circulars, the whole covering every branch of Science applied to the arts, sent free and free of postage to any one in any part of the world who will furnish his address.

THE GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA.

LIMITED.

TRADE MARK.

(McARTHUR-FORREST PROCESS)

MacARTHUR-FORREST PROCESS.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty. Advisory Board in the United States: Thomas W. Goad, Mgr; Hugh Butler, Att'y; John F. Bell; P. George Gow.

OFFICE:

McPHEE Building, DENVER, COLORADO.

Agency and Experimental Plant, Mechanical Arts Building, Midwinter Fair, San Francisco, Cal.

THE ROESSLER & HASSLACHER CHEMICAL CO.,

73 PINE STREET, NEW YORK.

TRADE MARK.

Cyanide of Potassium

Ferricyanide of Potassium

Red Prussiate of Potash,
K₂Fe(CN)₆

Ferrocyanide of Potassium

Yellow Prussiate of Potash
K₂Fe(CN)₆·3H₂O

Hyposulphite of Soda,
AND OTHER CHEMICALS.

QUARTZ SCREENS

A specialty. Round, slot or burr slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

MINE SURVEYOR WOULD LIKE A POSITION in some mine; can keep books, make a gold and silver assay and is a journeyman machinist. Will furnish good references. Address MINE SURVEYOR, 1725 Sutter St., San Francisco.

Electric Progress.

Expense of Electrical Engineering Business.

Sydney F. Walker says in the London *Electrical Engineer*: Probably few electrical engineers, except those who have been in business for a number of years, appreciate how very heavily all electrical engineering work is handicapped by the dead exposures involved in carrying on the work. The remark is true of all engineering businesses, but particularly of electrical engineering. Even the rapid advances, of which all electrical engineers are so proud, add considerably to the cost of working. Some new improvement is made, and not only patterns and drawings, but perhaps a lot of finished work becomes dead stock, of the value of old metal. When, too, as is constantly happening, one firm works out an improvement in some part of their apparatus, every other firm making the same class of apparatus must follow suit, no matter at what cost, or be left out in the cold when orders are given out.

It must be borne in mind, too, by those who think electrical engineering businesses so many veritable El Dorados, returning enormous profits upon small outlay, that the proprietors of an electrical engineering business have to make good, not only their own slips, but those of all their employees, and often those of the employees of other firms. To be successful, you must follow your work, see it kept right, no matter what it costs, or into whose hands it goes. If you do not, any breakdown is attributed, not to the apparatus being improperly looked after, but to the apparatus itself being improperly made. And unfortunately, too, electrical engineers are very much like women, in that they are rarely able to see any good in each other's work. Few electrical engineers, if called in to repair the work of another firm, can resist the temptation to condemn the rival firm's work. And so all these little things cost money, and a good deal of it. And besides all these, as every electrical engineer of experience knows, every now and then something turns up, some new developments of the laws of science that had not occurred to any one before, that often appears at first sight to be contrary to those laws, but which always lead to one result—additional expense, more or less heavy, for the manufacturer or contractor.

And the above are in addition to the regular expenses of all properly conducted businesses. Keeping accounts so that you may know what you are owed, and what you owe, and what your expenses really are, is an important and often a very heavy item in proportion to the business done. Even the correspondence of electrical engineers in business is heavier and more costly than that of other businesses. The thing is new, and buyers often require to be very sure of their ground. Misunderstandings are more likely to arise over work that is quite new to one of the parties concerned than where both are familiar with the principal details. And this necessitates the treasuring up of every letter that one has written or received for years after.

Securing orders is also, if one may judge by what one sees in other lines of business, a far more expensive matter in electrical engineering than elsewhere. Electrical engineers themselves are, perhaps, to blame for a large part of this. No sooner is it known that an order is in the market than the representatives of several firms rush for it, each bent on belittling all his rivals. Tenders, too, are a constant source of expense, and the writer believes affect electrical engineers more severely than any other business. People do not scruple, apparently, on the plea of asking for a tender, to put several firms to heavy expense, often without the slightest intention of employing any of them; sometimes, even, merely with

a view to obtaining information. All these things, and many others, cost money, and unfortunately the sum of them, when added up, bears a very heavy proportion to the amount of business done. With limited companies the amount is usually even higher.

The writer's object in penning this article is to endeavor to deter those who are engaged in electrical engineering businesses from the stupid practice of cutting prices. If you are to make a moderate profit out of your business, you must have a certain average rate of profit on your transactions, such that the sum it furnishes in the year will cover your expenses and leave you your modest profit. If you attempt to cut below this figure, whatever it may be, you will lose money and your business. If you attempt to cut your coat to your cloth, or, in other words, to make a profit by inferior work or materials, you will lose your business as soon as the results of your work have had time to show themselves. If you simply take the loss, carrying out the work as it should be done, you will lose your capital.

Transmission of Electrical Power.

Profs. Houston and Kennelly have made an exhaustive compilation of facts and figures to answer the question, "How far is it commercially possible to transmit water power electrically?"

The question of the long-distance transmission of electricity depends upon two factors: Cost, which includes the purchase and maintenance of the necessary machinery and wires, together with the annual interest chargeable thereon, and electric pressure—the pressure or voltage at which the line transmitting the power can be operated safely and permanently, and with perfect protection of the conductors from lightning, weather and all disturbances. Although water power has not yet been made available at a greater distance than 25 miles, it has been generally considered that it could be distributed commercially at a radius of 50 miles. Messrs. Houston and Kennelly say that, if reliable machinery can be bought cheaply enough, and the conductors can be safely operated at sufficiently high pressure, there is nothing to hinder the Falls of Niagara from stopping steam engines in New Orleans by underselling their power.

A point of the greatest importance is the nature and disposition of the conductors. Three methods have been advocated at different times: The conduit method, in which insulated cables are buried in underground pipes, containing air, or filled with oil; the subway method, in which wires are carried on brackets in an underground passage, as between many buildings at the World's Fair, and the ordinary aerial line method. Within city limits the first or second method would be indispensable, in order to secure safety from accidental contacts with high-pressure conductors; but in the open air, the overhead line is the cheapest, and it can be made, moreover, proof against lightning or sleet. This construction was employed between Lauffen and Frankfurt, and has been adopted in all the long-distance electric transmissions yet constructed. After a careful analysis of cost and the possibilities of electrical machinery, it is demonstrated that the power of Niagara Falls can be transmitted to a radius of 200 miles, cheaper than it can be produced at any point within that range by steam engines of the most economical type, with coal at \$3 per ton; furthermore, that, given a certain output, say 50,000 kilowatts, it might be commercially advantageous to undersell large steam powers at twice this distance with no profit, in order to reduce the general expense upon delivery nearer home. The difference in the transmission radius between small and large water powers hinges on the fact that electrical and hydraulic machines can be built and purchased much more economically in large sizes than in small, so that the cost of

producing and of maintaining one kilowatt is very much less for large than for small water powers.

The Origin of Spiral Wires.

More than one observing person, not familiar with electrical apparatus, has had his curiosity aroused by noticing that, in a great many pieces of apparatus, when installed, the wire immediately next to the appliance has been twisted in a neat coil, not unlike that of a spring. This curious feature is seen in the wire leading to telephones, push buttons, call bells and the like, while it may also be observed sometimes in the heavier wires which are attached to the "hanger boards" of arc lamps. As a matter of fact, these coils are not an essential element in any mechanism, though many believe them to be so; but are simply a symmetrical way of disposing of the slack wire that had been allowed in measuring the distance. So easily do we become imitative in our habits, that this traditional arrangement may now be noticed in a great many places where there is not the slightest necessity for it, and the most striking example is that furnished by a large electric-lighting plant in England, where the huge copper rods leading from the dynamos to the switchboard have actually been tortured into corkscrew spirals, in order to give them some kind of vague resemblance to the involutions attached to the smaller and cruder devices of bygone years. This is another instance of English conservatism, which is still manifested, as Herbert Spencer has noted, in the retention of the lines of the old stage coach in their most modern railway cars.

Another Amperian Rule.

Many rules have lately been published for fixing in the mind the relative directions of the electric current, and the lines of force of whirls surrounding it, and the author of the most recent method, Carl Hering, thinks it more simple and easily remembered than the others. He says that to remember the direction of the magnetic whirls around a current it is only necessary to bear in mind that if the current flows like the ink from a pen (that is, out at the point) then the direction of the whirls will be similar to that of a close spiral encircling the pen, and begun as if one started to write the small letter "m" (magnetic lines). If, however, the whirls be drawn counter clockwise, as though writing the letter "c," the current represented by the flow of ink down the pen will be the one induced by the generation of these lines, as in transformers.

Practical Information.

Figures Show Differently.

In a curious article, "The Number of People Since Adam," the author asserts that "the whole surface of the globe has been dug over 120 times in order to get room for burial places." The *St. Louis Republic* don't believe this, and has gone into mathematics to prove its falsity. In 6000 years we have had 60 centuries, and in each century an average of three generations, or 180 generations in all, each being a generation of 1,500,000,000. Give to each man, woman and child a grave 5 feet by 2, or 10 square feet. A square mile contains something less than 28,000,000 square feet. If this last calculation be correct, you will have to have a cemetery 55 miles long by 10 wide for each generation. Now multiply this by 180, the whole number of generations since Adam, and you have a burying ground large enough for every human being that has died in the last 6000 years.

This vast cemetery, though awful to contemplate, would be but 1800 miles long by 55 miles wide, or, in order to get it in better proportion, say 220 miles wide and 550 long.

In other words, a burying ground containing 100,000 square miles would be sufficient for the graves of every human being that has ever existed. The area of Missouri and Iowa combined should be amply sufficient for such a cemetery, with 22,425 miles left for walks and driveways.

If the calculation is carried out for 100,000 years instead of 6000, it will be found that the cemetery need only be a square of 1700 miles in extent each way. On this basis the United States east of the Mississippi river is large enough to furnish a grave for all the human beings that have died during the past 6000 and for 94,000 years to come.

What Is Chemistry.

Everybody who thinks must be impressed by the great variety of things found on this earth, and the question, What does the earth consist of? must often suggest itself. Among the most important results reached in studying the things around us is this, that notwithstanding their great variety they are made of simple things, and these in turn of still simpler—that there are, in fact, only about 70 distinct kinds of matter, and that all the complex things around us are made up of these seventy elements. The solid crust of the earth, as far as it has been possible to investigate it, all living things, both animals and plants, the air and water, consist essentially of twelve elements. The elements do not, as a rule, occur as elements. They are generally found in combination with one another. Oxygen and nitrogen are, to be sure, found in the air as elements, uncombined; but such familiar substances as water, salt and quartz consist of elements in combination. Thus water consists of hydrogen and oxygen. Hydrogen, the element, is a colorless, tasteless, inodorous and very light gas that burns readily. Oxygen, the element, is also a colorless, tasteless, inodorous gas. It does not burn, but burning things burn with much increased brilliancy in it. When hydrogen and oxygen are mixed together in a vessel under ordinary conditions, no action takes place. They mix thoroughly, forming a mixture that is also a colorless, tasteless, inodorous gas. If a spark is applied to this mixture a violent explosion occurs, and this is the signal of a great change. The two gases have entered into chemical combination; they are no longer the gases hydrogen and oxygen; they have entered into combination and now form the liquid water, a substance with properties entirely different from those possessed by the constituents.

Again, chlorine, the element, is a greenish-yellow gas that acts violently upon other things and causes changes in them. Inhaled even in small quantity it gives rise to distressing symptoms, and in large quantity it causes death. Its odor is extremely disagreeable. Sodium, the element, is an active substance that has the power to decompose water and set hydrogen free. When chlorine gas is brought together with sodium, the two combine chemically and form the well-known compound salt, or, as the chemist calls it, sodium chloride. From this the elements chlorine and sodium can be obtained by the chemist. These two examples serve to show what is meant by chemical combination and by a chemical compound. Chemical compounds are generally found mixed with other compounds. This is shown, for example, in many of the varieties of rocks, as granite, which consists of three different chemical compounds. It is shown much more strikingly in living things, all of which are made up of a large number of chemical compounds, mixed, to be sure, not in a haphazard way, but beautifully adjusted and working together in wonderful harmony. Just as elements combine chemically to form compounds, so elements act upon compounds and cause changes in their composition. Thus oxygen is constantly acting upon other things, sometimes slowly but, in the case of fire, rapidly and with

tremendous energy. It is commonly said that fire destroys things. In fact, it changes their composition, and the principal products of the change are gases. This kind of chemical change is the most familiar that is brought about by the action of an element upon compounds. Compounds, too, act upon compounds, and cause an infinite number of changes in composition. Thus the food we partake of consists of chemical compounds. In the body these compounds find others and they act upon one another so as to repair the wasted tissues and cause growth. The gas known as carbonic acid, that is contained in the air, acts upon the compounds in the leaves of plants and causes changes that are absolutely essential to the life and growth of the plant.

Look, then, in any direction and you will see evidence of changes in composition that are constantly taking place, and that are essential to the existence of the world as it is. These changes in composition and the compounds themselves that are involved in the changes form the subject of chemistry. In the light of what has been said, it is clear that chemistry must be a very broad science. Remembering that chemical action is the cause of the formation of chemical compounds, that without chemical action the compounds would cease to exist, and would be resolved into their elements, it is impressive to think what would take place if chemical action would cease. Most of the things familiar to us could not exist. The solid portions of the earth would, to a large extent, be replaced by the element silicon, something like charcoal, and by oxygen and a few metals such as sodium, potassium and aluminum. Water would be resolved into the two gases hydrogen and oxygen. All living things would fall to pieces, and in their place we should have the gases, hydrogen, oxygen and nitrogen, and the solid element carbon, most familiar to us in the form of charcoal. Life would, therefore, be impossible.—Chautauquan.

They Fall Up and Get Hurt.

The fish that live at enormous depths are, in consequence of the great pressure, liable to a curious form of accident. If, in chasing their prey or for any other reason, they rise to a considerable distance above the floor of the ocean, the gases of their swimming bladder become considerably expanded and their specific gravity greatly reduced; up to a certain limit the muscles of their bodies can counteract the tendency to float upward and enable the fish to regain its proper sphere of life at the bottom, but beyond that limit the muscles are not strong enough to drive the body downward, and the fish, becoming more and more distended as it goes, is gradually killed on its long and involuntary journey to the surface of the sea.

The deep sea fish, then, are exposed to a danger that no other animals in the world are subject to—namely, that of tumbling upward. That such accidents do occasionally occur is evidenced by the fact that some fish, which are known to be true deep sea forms, were discovered dead and floating on the surface of the ocean long before our modern investigations were commenced.—Popular Science Monthly.

THE average senator smokes an expensive cigar. There is a 35-cent brand which sells more readily than any other in the Senate restaurant, and which is in great demand for committee-room lunches. The Southerners, who, as a rule, have to live on meager incomes, are the most expensive of all in their taste for tobacco.

A METEORITE of 267 pounds, found by Prof. A. Heilprin, in 1891, near Godhaven, Disco Island, has been pronounced tempered steel, its extraordinary hardness having possibly resulted from rapid cooling in snow, ice or water. It contains iron, nickel, sulphur, traces of carbon, chlorine, phosphorus and chromium.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes thereof from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Opelet; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tests.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 181 pages with illustrations and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

American Silver Product.

Director of the United States Mint President estimates the silver product of the United States for the calendar year of 1893 at 60,000,000 ounces, which is nearly 2,000,000 ounces more than for 1892. This, says the *Bulletin*, is something of a surplus in view of the great depression in the price of silver last year. The greatest three producers of silver in this country are Colorado, Montana and Utah in the order named, though 15 other States contribute to the total. Four of these are Southern States, and their product is measured by a few hundred to a few thousand ounces. States and Territories producing over 1000 ounces compare as follows:

	1892.	1893.
Colorado, ounces.....	24,000,000	25,838,600
Montana.....	17,350,000	16,906,400
Utah.....	8,100,000	7,196,300
Idaho.....	3,164,269	3,910,700
Arizona.....	1,062,220	2,935,700
Nevada.....	2,244,000	1,561,300
California.....	360,000	370,100
New Mexico.....	1,075,000	458,400
Texas.....	210,000	349,400
Washington.....	150,000	152,700
South Dakota.....	60,000	149,400
Michigan.....	60,000	43,500
North Carolina.....	9,000	13,400
Oregon.....	50,000	11,800
Alaska.....	8,000	9,600
Other States.....	1,800	1,700
Totals.....	58,004,289	60,000,000

The product from the other States come from Georgia, South Carolina and Tennessee. The coining value of the product of 1893 is given at \$77,575,757, against a coining value of \$74,995,442 in 1892. This means, we suppose, that if all the silver produced in the United States in the past two years were made up into 412½-grain dollars the product would be as above stated. The commercial value of the silver is of course its gold value, which for both years was much less, that for 1893 not being much more than a little over one-half of the coining value. The coining value of the silver produced in this country is still more than double the coining value of the gold produced.

THE deepest artificial hole in the earth is at Poroschowitz, in the Rybnik district, Upper Silesia. It has been carried to a depth of something beyond 2000 meters (about 6700 feet), and the diameter of the tube at the bottom is seven centimeters. Boring at such depth, and, moreover, through solid rock, was almost impossible prior to the invention of the Mannesmann tube; the greater strength of this tube, as compared with others, makes it possible to use tubes of thinner gauge. It is expected that a final depth of yet another 500 meters (some 1670 feet) can be reached, and a number of interesting observations on temperatures, etc., will be made.

IRON ORES are considered rich when they contain above 50 per cent of iron, average when they contain between 50 and 35 per cent, poor when they contain between 35 and 25 per cent, and useless when below 25 per cent.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

DEEP WELL PUMPS

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhes Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Calaveras.

LIVELY TIMES AT ANOALA.—*Amador Record*, May 17th: They are having lively times in Angels. A number of workmen who were employed in the Lane mine are on a strike at present and threaten to blow up the mine. The superintendent is somewhat apprehensive, and he has taken precautions to prevent the carrying into execution of the menace. The mine has ceased operations, and a guard of five armed men is kept on duty night and day. An outbreak is feared at any time. A vigilance committee of citizens to the number of 600 has been organized to clear the camp of objectionable characters. A number of the undesirable class have received notices to decamp. Some have left already, but others declare that they will remain. The citizens are determined, however, and assert that if they do not depart of their own volition they will be driven out of the town by force.

Los Angeles.

MUCH GOLD IN SIGHT.—*Los Angeles Times*: L. R. Harrison of this city has returned from the Red Rock mining district, 23 miles north-east of Mojave, where he has several valuable claims. Mr. Harrison brought with him a pocket of nuggets to show what he is doing. He says that with primitive dry washers men can make good wages, and if water can be got on the claims, there is high money in sight. The gold is on top of the ground, and the dirt is easily worked. He has great hopes of the Red Rock camp.

Madera.

The works of the Mammoth Mining and Milling Co. are situated in Madera county, this State, on the stage road to the Yosemite valley, and distant from that locality about 60 miles. The ore is rich in tellurium. The power house of the company is one and one-half miles from the mill and mine, on the Fresno river. Eighty inches of water are carried in a flume and ditch, obtaining a fall of 70 feet. The power from the Pelton wheel in use is transmitted by a 900-foot one and one-quarter-inch cable to a three and one-quarter-inch counter-shaft and a 100-horse power generator by a 24-inch belt, generating 1000 volts. B. C. Van Emmens is the electrical engineer of the company. The electricity is transmitted by a wire from the power house to the mill, there being a loss of not to exceed five per cent in the three miles of wire. The shaft is at present 600 feet deep, good ore being found in the north drift. A 10-stamp mill is in constant operation, and the concentrators are doing good work.

Mono.

MINING NOTES.—*Miner*: Supt. Kelly maintains an impenetrable silence relative to the strike in the Bodie, apparently not wishing to take the public into his confidence. The mine is closed to visitors, and we have no means of obtaining information for our readers. It is the prevailing impression, however, that the ore is very rich, but the extent of the body is not known, beyond the fact that last week the ledge was officially reported to be five feet wide.

The Bulwer commenced milling ore at the Standard last week. Five stamps are busy crushing, and it is expected the run will continue till about the 1st of next month.

The Bodie mill is being put in shape for a run on Bodie ore.

Operations on a small scale were resumed at the Mono this week, a few men being put to work to clean out some of the old drifts.

Ore is being hauled from the University to the Miners' mill, which will be started up in a few days.

Nevada.

CLEANUP.—*Grass Valley Union*: A cleanup was made at Gauthier's mill yesterday of ore from the Granite Hill mine. Superintendent Waggoner could not be seen, but it is reliably stated that 50 carloads of quartz crushed yielded \$3200.

Plumas.

BIO YIELD OF GOLD.—*National Bulletin*: Word comes from Prattville that, in five days, Fred Scott had taken from the King drift mine, on the North Fork, the sum of \$700 in channel gold. We are glad to hear such good news. This property is at the lower end of Big Flat, through which, for a distance of nearly four miles, an ancient auriferous channel runs. The Glazier mine is at the upper end of the Flat, and the Angus Cameron mine is near the center.

Shasta.

IRON MOUNTAIN.—*Courier*: Preparations are being made to start up the Lost Confidence mine, which has not turned a wheel since the depression in silver.

Free Press: A rich body of ore has been encountered in the Texe Consolidated mine at Old Diggings. Not long since the fifth lowest tunnel was commenced, which was expected to tap the main ledge at a distance of 1700 feet. But already they have struck ore which assays over \$1000 to the ton.

San Bernardino.

The mill of the Morongo King Mining Company, of which C. W. Allen is president and Judge Campbell is a principal owner, is all completed and ready to start up on a large amount of ore already mined as soon as the pipe line is completed. It is thought that this will be about the 20th.

Word has just reached San Bernardino of a very important strike in one of the mines of the Altuna Mining Company, in the Morongo

district. A tunnel 145 feet long has been run, which tapped the vein at a depth of 75 feet below the surface. At this point a body of rich ore, running from \$200 to \$300 per ton in gold, was found. A drift has been run on the vein about 25 feet, and about six tons of rich ore have been taken out and sacked for shipment. The ore body is about 2½ feet wide and is continuous so far as the development work has been carried.

NEVADA.

Washoe District.

In the Con. Virginia the south lateral drift No. 3, from west crosscut, 25 feet below sill of floor, 1650-foot level, is extended 21 feet. The first two feet are in low-grade ore, the remaining 19 feet in solid ore, and steadily improving in quality. The average assay value is about \$60 per ton per car sample.

The face of the drift is in higher grade ore, the average value of which is now over \$100 per ton.

It is evident that the ore found in this drift is the continuation and extension of ore developed in the two south drifts above.

The weekly ore output is 139 carloads—about 137 tons; the average assay value per car samples, \$39.54 per ton.

The ore was taken chiefly from the two south drifts, 14 feet above; the remainder of lower grade from the vicinity of the winze, 20 feet down. The workings from the Rule drift are in porphyry.

Silver Star District.

Hawthorne Bulletin: Three tons of ore from the Oneida (the first lot milled from the new camp) yielded \$65 per ton in the arrastra last week.

A lot of about 13 tons from Ed Brown's Hardscrabble is at Soda awaiting shipment to the Taylor mill at Silver City. It is expected this ore will mill over \$100 per ton.

Mr. Matthews (expert for Senator and Sam Jones) visited Silver Star last Friday. He says he never saw a camp that showed as much gold for the work done as our new camp shows.

A letter from Arthur George yesterday reports four inches of \$150 ore in the bottom of the Oneida incline, 50 feet deep.

ARIZONA.

A new and fabulously rich gold find is reported in Santa Maris, in western Arizona, and is causing a stampede of miners everywhere. The locators are C. S. Black, J. Bohner, B. Breckman. Twenty thousand dollars was offered a few nights ago for a third interest, and flatly refused by Black. The locators are well known in Prescott and are perfectly reliable men. Miners are very reticent. Four thousand feet of ledge have been prospected and located. The locality is almost inaccessible, and parties are preparing to go out. It is supposed to be the Nigger Ben mine, that men have spent thousands of dollars to find, and years of labor. The new discovery was purely accidental. Years ago thousands of yards of placer dirt were found near the location. Water is not to be had.

FINANCIAL TROUBLES.—*Journal Miner*: The financial troubles of the Henrietta Mining Company still remain unsettled. They are said to have been caused through an agreement to apply 50 per cent of all the hullion taken out on the payment of the mine, and there is scarcely a mine in the world that would permit of 50 per cent of its gross receipts being taken out and then have sufficient left to pay for mining and milling the ore and for development work in the mine. The employees of the mine are said to be in possession of the last cleanup of hullion, amounting to \$2000 or less, which they are holding until they receive their pay for work. Honest and reliable miners, who have been employed in the mine, state that it is no fault of the mine that the present difficulties have arisen. Just prior to the closing down of the mine a large body of ore was struck, which gives an assay value of over \$100 per ton in gold.

A new mining venture, and one which gives promise of success, is that of Messrs. Buchann, Little and Rice in Buckhorn gulch, a tributary of Castle creek. It is a placering proposition, and one that is to be thoroughly and somewhat extensively worked. The first shipment of machinery was taken by wagons yesterday, and is to be followed by another immediately. The promoters of this enterprise have thoroughly tested the diggings and will adopt the old method of eluding the ground, an abundance of water being secured adjacent, which will be conveyed to the claims by pumping machinery that is now on the road. That section has been the scene of considerable placer mining by Mexicans in years gone by, but as it was of a purely surface nature, no reasonable idea could be formed of the value of the ground at bed-rock until these energetic men made a "sample run." The new plant will be in operation inside of a month.

TO SMOKE LEAD CARBONATES.—*Arizona Citizen*: The lead carbonates for Colorado smelter average about 8 per cent lead, while for good work melting they should run at least 12 per cent. In Arizona are some large bodies of lead—two in particular, one of which will run as high as 60 per cent. A prominent melting company has in view the removal to Tucson, or the building of branch works here. They have a great deal of ore from Arizona, and know the field well justly them. Should it be built they want it to take in all Arizona, and not be merely a local affair. For this they want direct railroad communication with the Sonora ore fields, also with the great ore bodies of northern Arizona.

BRITISH COLUMBIA.

YALE DISTRICT.—*Kamloops Sentinel*: A party of three prospectors who came from California a short time ago, passed up the North Thompson river lately with a pack of eight animals.

They propose going as far as the headwaters of the Clearwater. They will be gone all summer and have a good supply of provisions.

The Prince Albert Flat Hydraulic Mining Co. has now the monitor working on its property near Yale, but so far has been removing comparatively barren ground to get to where the pay dirt is expected to be found. The cost of putting on the water was comparatively low and high profits are expected.

COLUMBIA RIVER PLACERS.—*Kamloops Sentinel*: Messrs. Parker and Leavenworth of Seattle, representing a New York syndicate, have decided to take over the large area of placer ground, starting from the boundary adjoining Fort Sheppard and running south along the Columbia river for two miles. They will at once commence the building of a \$30,000 ditch, to bring the water onto the ground from Cedar creek.

It is reported in a Victoria paper that the trial made at Yale by Bell & McCastle's gold dredger fully realized the highest expectations of the prospectors. Working in 12 feet of water gold gravel was pumped up from the bed of the river, which yielded 194 ounces of gold in a 36-hours' run. Stones weighing 25 and 30 pounds are brought up by the pump, and the whole machinery works perfectly.

COLORADO.

THE COLUMBUS MINAS.—*La Plata News*: Supt. McDermott will soon commence work on the Columbus mines. Horses will be built, the road repaired and a tunnel started below the falls and run 800 feet, which will give a depth of about 300 feet. Last fall this mine was examined by Mr. McDermott, who was highly pleased with it. He took 500 pounds of the best ore to Denver, from which, it is said, he obtained a gold brick worth \$16,000. This he took to Chicago and organized a company to buy and work the Columbus. The company took a bond and lease on the mine. A working capital of \$100,000 is available, and plainly indicates that the company means business.

THE JACKSON PROCESS.—Tests by the Jackson process for the extraction of the precious metals have lately been made at Lake City, fully demonstrating that ores costing \$15 per ton for smelting can be treated by it for from \$4 to \$8 per ton. The following description of the process has been handed the *Record*: "The ore is pulverized to 50 or 60 mesh fine, then roasted till the volatile impurities are driven off and the ore becomes sweet. A mixture of ores are generally used, so that one may act as a flux to another. After roasting the ore is chloridized, cooled and placed in tanks, where the base metals are dissolved out with water, leaving the gold and silver as chlorides, which are dissolved by a solution composed of hyposulphite of sodium and salt. The gold and silver are then precipitated by electricity, the precipitates are then washed, dried, melted and run into bars ready for shipment." The West End Gold Mining Company, at Sherman, on whose ores the test was made, will, as soon as plans can be prepared, erect a plant of 50 tons daily capacity and operate it under the process.

An excitement has been created at Cotopaxi by a large gold find which was made 18 miles north of that place. The specimens exhibited are rich, and there was a rush for the new field.

SOLD AT SHERIFF'S SALE.—The Railroad Boy mine and mill site, the Independent mine, the Denver and the Clear Falls mines, the property of the Gold King Mining and Milling Company, and located at Salina, have been sold at sheriff's sale, under three separate executions, to Mary G. Arnett, of Boulder, for \$3923.44. This same property was held at \$150,000 last year.

WORKING ZINO MINAS.—The old zino mines at Cotopaxi have resumed operations. Ten men are employed.

CLEAR CRAK.—The Empire correspondent of the Georgetown *Courier* says: Empire's mines are showing up well. The Crown Prince has a large streak of \$30 iron ore. The Cleopatras is truly a mine of beauty and has a fine streak of quartz and iron worth from \$60 to \$100. The quartz streak in the Badger Boy is as big as ever, and in the language of Mr. Clark, is simply red hot. The Gold Dirt streak gets larger as the boys go down on it, and is worth \$70. The streaks in the Tenth Legion have not pinched out by any means, and the iron is worth \$25 to \$75, while the quartz is worth from \$100 to \$160 per ton.

COLORADO SPRINGS.—The statement of the *Gazette* that there were 800 idle, starving and desperate miners on Bull Hill is being severely censured by mining men. Those best posted say that there cannot possibly be over 200 or 250 men idle because of the strike, and those could secure work at \$2.75 per day for eight hours if they chose.

PARK COUNTY STRIKES.—*Denver Record*: A report is just received from Alma, Park county, that a wonderfully rich strike has been made in the U. P. and K. P. gold mines in Mosquito gulch. Assays from select ore run as high as \$6000 per ton. It is claimed that the melting mill will average several hundred dollars per ton with a high body of rich milling ore. These are contact veins of porphyry and lime, and porphyry and quartzite. A carload of this will be shipped in a few days. A report also comes of a new body of ore of higher grade than usual in Black Flag, situated between the U. P. and K. P. mine and the Macotte gold mines.

TELLURUM.—One hundred and seventy sacks of tellurium ore have arrived at Creede, from the Good Hope mine at Bear creek, and was shipped to Denver. This ore is estimated to run about \$700 to the ton. Assays have been had from ore at the grass roots from Bear creek, giving 13 ounces in gold per ton.

THE GOLD FIELDS OF ALMA.—Placer mining is now under full headway at Alma, Fair Play,

Beaver creek and Tarryall. At Alma, day and night shifts are on, new flumes and ditches have been constructed, and the great streams from the nozzles of the hydraulics are tearing down the banks of gravel and gathering the gold as no other process can. The dirt being washed at the new workings is the richest yet encountered, and this year's harvest will surely be a rich one—richer than those of past years, which are said to have yielded an average of \$20 per day to the man for the season.

One of the good indications of the present is that there are no idle men around Alma, and few, indeed, in the county. They are all at work—if not on a wage scale, they are leasing, prospecting or developing properties.

This side of the county has many mines that should be worked—mines that are developed and proven, mines that have great ore bodies in sight, and that, carefully managed, would pay big dividends. Among these is the London of Mosquito, directly between Alma and Leadville, one of the greatest mining properties of the State, but unfortunately owned by Eastern millionaires who do not care to work it. The property is well developed, has a fine mill at the mine, and eight miles of road tap Mosquito gulch from London Junction to the mill, its own property, aside from a tramway from the mine down to the mill. From this group gold ore was exhibited at the World's Fair which yielded over \$40,000 per ton. It may also be added in proof of the richness of gold in these districts, that gold ores from Mount Cross have been marketed in the past, giving returns as high as 600 ounces, the same ore containing 500 ounces in silver.

The Lee Gos and First National, Montgomery mines, belonging to the Green Mountain Mining Company, which have many thousands of tons of gold and copper ores in sight, are expected to be put in active operation this season.

TARRYALL DISTRICT.—Warm weather and rain have hastened the disappearance of the snow in the Tarryall district, and mining operations have taken on new life. New cabins are being built, and work on the new stamp mill is progressing fast. Streams are now running, making placer work possible. Leland Peabody is employing 40 men on his placers in washing, in addition to a force of men employed in the construction of an immense reservoir. Mr. Peabody has employed Chinese in washing gold for a number of years past, but this year he has given preference to white men.

IDAHO.

POORMAN.—*Avalanche*: The rich ore in the north drift of the Oso in the adit tunnel continues without change. A raise is being made for stopping. In the south drift a nice streak of ore is coming in on the hanging wall which promises to equal that in the north drift. We were permitted by the management to look at the assayer's report from samples taken from the east or hanging wall, which were as follows: No. 1, 561.2 ounces silver and \$1232 in gold; average, full 50 feet, 636 ounces silver and \$864 in gold. Picked samples would, of course, assay much higher. In the Oso, or No. 3 tunnel, drifting and stoping is being done. The face of the drift is all ore, the full width of the tunnel. In stope No. 1, they have opened a lot of "Poorman butter," or "mineral talow," which is full of nuggets. This ore is a characteristic of the old Poorman. New stopes have recently been started, numbered from one to eight inclusive. Each stope is 50 feet in length, all connected. The ore body varies from twelve inches to the full width of the vein. In one stope there is not sufficient waste to keep the "floor" up, making it necessary to blast into the walls to obtain waste for that purpose. The outlook on the Poorman is most flattering. The mill is pounding steadily.

ORO FINO MINAS SOLD.—*Avalanche*: The Oro Fino mines, limited, have been sold by the sheriff to T. Regan at \$159,362.88. The Oro Fino is one of the large properties of War Eagle mountain and the last on the far-famed Chariot vein to be worked. We attribute the cause of the company's failure to the large amount of water which it had to contend with in working the mine. To raise the water from the Oro Fino it was necessary to drain all the adjoining properties, as the vein is open and accumulates water rapidly. With a tunnel tapping this vein from South Sinker, draining the same, every property on the belt could be worked at a profit. Unless we misread our guess, preliminary work upon this enterprise will be started this summer; and if started, will be pushed rapidly to completion.

CRUSHING QUARTZ.—*Democrat*: The first quartz mill ever put up in the immediate vicinity of Boise is now and has been for some time dropping stamps within five miles east of town. It is crushing rock taken from the ledge bought of James Flanagan, and is said to be doing splendid work. Ten or twelve tons per day are crushed. Fifteen men are employed in the mine and mill, and the rock taken out is reported to be fine.

MONTANA.

PROSPECT THE DRY GULCHES.—*Dillon Tribune*: If you go prospecting this summer, and it seems quite likely to be the occupation of a good many men, give the numerous dry gulches which abound in these mountains an examination. It is the theory of the man on whose suggestion this is written, that the dry gulches are as likely to contain pay gravel as are those containing living streams. At any rate the matter is worth looking into, and if you strike pay and cannot work the ground yourself for lack of water, you can find some one with means who will take it off of your hands at a remunerative figure; there is no doubt about that.

The Bimetallic Mining Co. of Phillipsburg is remodeling its plant for the purpose of leaching the tailings belonging to them and also those of the Granite company, aggregating

about 400,000 tons. This plant will have a capacity to leach some 300 tons per day by the Russell process, which has already been tested and found a success. It is probable that the Bimetallic company will adopt the Russell process in treating its ores and thus do away with the amalgamating machinery in its mill. These improvements to the plant have been in process of construction ever since last fall and will be ready to begin operations in 80 or 90 days. The erection of a building for the leaching works, etc., will, when completed, have cost about \$75,000, and it is probable that later a plant for refining the bullion, similar to the Marsac machinery at Park City, will be put in.

AROUND BUTTE.—*Inter-Mountain*: All the mines of the Butte & Boston company which suspended work owing to the Great Northern strike have resumed and are being worked as usual. Owing to the absence of Captain Couch of the Boston and Montana, the usual number of men at some of these properties are not now employed, but it is believed that shortly all of the mines will be worked by a full complement of men. The copper market is improving, the demand for electrolytic copper continues and prices have been fairly satisfactory. Everything points to an active season's work in the copper industry, and the inquiries for copper properties by Eastern capitalists speak well for the future of this locality.

The Anaconda properties are being worked on their usual magnificent scale, and regular shipments are being made to the smelters. The new converter plant, which has a capacity of turning out 10,000,000 pounds of copper each month, is hard at work.

Among the silver producers of the district there is very little activity. At the Czarina and Jennie Dell the rich strikes recently made at these properties will keep the lessees busy for a few months, but at the present price of silver there will be no big money in it for anybody. A number of leasers are yet engaged around Walkerville and west of Missoula gulch, but beyond the fact that they are working hard to open up pay ore ground, they have nothing to report.

Placer mining will engage the attention of a larger number of prospectors this year than ever before. The water supply for the season will be adequate for all purposes on account of the heavy snowfall of the past winter, and few districts where colors exist will be neglected. There is said to be good diggings over in Granite county west of Phillipsburg, but as this season for work is short and the distance to bedrock great, little work has been done there. A number of Butte men are now outfitting for a trip there when the snow goes off the mountains, and they will no doubt thoroughly test that section for gold deposits.

NEIHART.—*Area*: Andy Nelson and Duncan McDonald have gone to work on their lease on the Cornucopia. They have been prospecting around the property with a view to find the most promising place to work in. Considerable ore has already been taken out by these gentlemen, and by the time the railroad is running again they expect to make quite a shipment.

The Grand Prize and Enterprise have been leased and bonded by James Garner and Wm. Rutkins. This property is located at the head of Rock creek and belongs to J. L. Neihart and Wm. Crandall. Very rich float was found all over these claims and two veins of good ore discovered. A tunnel 350 feet in length has been run on one of these veins and a depth of 125 feet gained. The ore in this vein is not very high grade, but it is hoped to find something better either further on in this vein or on the other, which has not been opened up to any extent. The lease and bond run for a year and the price stated in the latter is \$52,000.

ELK CREEK MINING DISTRICT, DEER LODGE COUNTY, MONTANA.—*Anaconda Review*: Twenty years ago Bear gulch was famous for its rich production of placer gold. Inside of three years three gulches were completely undermined by ground sluices, bedrock drifts and surface mining. Only the cream of the gulch was taken out. If the ground would pay \$20 per day to the man it was considered fair diggins; anything less was left. Wages were from \$10 to \$12 per day, and everything else in proportion. To-day \$3 a day to the man is considered enough to pay working the ground over.

The Bear Gulch Hydraulic Mining Co. have three miles of ground patented in Bear and Deep Gulches, through which they are running a bedrock flume, for the purpose of cleaning up all the ground as it comes in these gulches. They have perfect control of the water and every foot of ground from the face of the side mountains to bedrock is carried through the flume by 800 inches of water, divided into two pressure pipes and two waterfalls into the head of the ground sluice.

Last year they cleaned up \$20,000 in three months, about half of the time being devoted to work on the flumes and the construction of a tunnel 300 feet through a mountain peninsula in the gulch to get grade for a tailings dump. This has been accomplished, giving them dump ground for 25 years, if necessary, to work out the two gulches.

BASIN.—*Times*: The Lone Star put its machinery in position this week, the water was pumped out of the shaft, and the work of sinking to the 100-foot level was resumed. There is not much water to contend with, and work is progressing rapidly.

The Empire lode is situated just east of the Mantle. It has a vein of ore about three feet wide that will assay \$28 in gold and \$6 in silver. A tunnel is in a little over 100 feet, and a shaft is down 30 feet, and the ore looks good in both places. The claim adjoins the Champion on the west.

James Judge and Jack Wall have an immense amount of free-milling ore in the Mountain View, going from \$3 to \$6 per ton in gold on the surface. They have a 30-foot shaft on

the property and 60 feet of a tunnel, but it will have to be run 40 feet farther before they will strike the pay chute under the shaft.

NEW MEXICO.

The Ivanhoe Mining and Smelting Company's smelter at Ivanhoe is running. The smelter is turning out five tons of copper matte every 24 hours. This matte carries 60 per cent copper, 40 to 50 ounces silver and one ounce of gold per ton. The ore body in sight in the mine is over 20 feet in width, and sufficient ore is now developed in sight for a year's constant run.

The Texas mine shows no diminution of the ore bodies. Another shipment of rich ore is nearly ready to send to the smelters. The returns from the last shipment of two lots of ore and one lot of concentrates were as follows: Ore, Lot No. 1, 338 ounces silver and one ounce of gold per ton. Ore, Lot No. 2, 274 ounces silver and one ounce of gold per ton. Concentrates, 407½ ounces silver and 74 ounces gold per ton.

The Silver City *Enterprise* says that one of the biggest strikes ever made in New Mexico has been made in the Graphic mine at Hadley, near Cook's Peak. The new strike is on the 625-foot level, and the ore body is the full width of the drift, over four feet in width. The ore is richer and of better grade for reduction works than any ever found in the mine before. T. G. Condon, of Colorado Springs, president of the Silver City and Northern railroad, is largely interested in the Graphic. From all indications the new ore body is of great extent.

THE CHAMA PLACERS.—Photographer T. J. Curran has returned to Santa Fe from the Chama river, where he took some 20 views of the Bucyrus placer Company's new mill and 12 views of scenes along the river, showing those immense deposits of gold-bearing gravel. He says the success of the Bucyrus principle of saving this fine gold has been fully demonstrated by this mill, only it is found that the machinery in some parts is too light to make the profits what they should be. Accordingly, Robert Hunter and his New York backers are now having built at Buffalo a mill that is four times stronger than the one now in use. Mr. Curran also met Mr. Joyce of Montreal, partner of A. Cockburn, who has extensive placer holdings on the Rio Chama. Mr. Joyce says a \$40,000 Bennett machine will be in operation at their camp shortly. It will be put in on a guarantee to save the gold and will be run by electricity.

THE LEGAL TENEE.—What is reported to be a valuable strike has just been made in the Legal Tender mine, in the Moreno district, four miles from Elizabethtown. They have a 240-foot tunnel in which is uncovered a two-foot vein of ore which mills \$200 in gold, with 60 ounces of silver and from 8 to 10 per cent in lead. C. W. Watson, late of Colorado, is pushing developments on this mine.

OREGON.

Democrat: A rich pocket was found last week in pursuing work in the long tunnel of the Connor Creek Mining Co. The amount of gold taken from the pocket is valued at \$90,000 and the last of the golden treasure was taken out last Saturday evening. The Connor Creek mine up to about two years since was a steady producer of from \$20,000 to \$40,000 per month; but finally the ledge was lost, since which time Capt. Myrick has had a force steadily employed running a large tunnel in the hope of tapping the old vein at greater depth. The tunnel is now about one and one-half miles long. It is in this tunnel that the find of last week was exposed. Such a find is truly wonderful, but where pockets exist the treasure vaults may contain a larger as well as a lesser amount. Gold is where you find it and in peculiar shapes, form and quantity.

Courier: J. C. Lewis is now running three tunnels night and day on Mt. Reuben. One of these bores is over 400 feet in the mountain, and the owners think 200 feet more will strike the ledge 1000 feet below the surface. The ledge has been followed on its highest level by a 600-foot tunnel, and the lode proves from 12 to 30 feet in width. This will be the deepest mine in Oregon when finished.

SOUTH DAKOTA.

REVIVAL OF PLACER MINING.—Deadwood *Pioneer*: Since the revival of placer mining, there has been more placer gold sold in this city than at any time since the palmy days of 1878 and 1879. The banks, jewelry establishments and assayers buy large quantities daily. Every creek in this part of the Hills is dotted in length with flumes. The revival of this class of mining was caused by the closing down of the Central and Terraville mines. The miners were compelled to earn a livelihood, and this being a means, accepted the means with more success than was anticipated. Of course no such returns are gathered as were in the virgin bare of the creek in the early days, but nevertheless \$5 per day is easily gotten per man, and in some places even more. From the early days until a few days ago placer ground that would not produce richly was let severely alone, but now this mode of mining is resorted to for a living and it bids fair to grow into an industry that will add greatly to the gold production of the Hills for 1894.

UTAH.

Tintic District.

HAVE A BONANZA.—*Park Record*: Every man who has lived in Utah any length of time knows of the famous Copperopolis mine at Mammoth, in the Tintic district, and of the large amount of rich ore it has produced. Many have also heard of the Champlain claim adjoining, which has been worked for several years by different parties under lease and bond. A controlling interest of the latter claim recently came into the possession of W. I. Snyder and

Stamp Cam.

Judge Henry Shields, of this camp, and has been worked by them under the management of J. M. Sullivan, and with a full knowledge that the Copperopolis people were taking ore out of their ground, for they could plainly hear the men working beneath them. Thursday of last week the men working under Mr. Sullivan broke through, having followed the ore for many feet. The result was that the owners of the Copperopolis procured an injunction from Judge Smith of the First District Court at Provo, restraining Messrs. Snyder and Shields from taking ore out of their own ground, and setting May 19th as the day for them to appear and show cause why the injunction should not be made permanent. The gentlemen anticipate a stubborn fight, for the ore in the Champlain is very rich in gold, for two shipments recently made by the Copperopolis of ore stolen from this ground averaged \$10,500 per ton for one lot and \$3000 per ton for another. The ground is worth fighting for, and the Champlain people propose to have their rights if it is possible to obtain them in the courts. They have demurred to the injunction issued against them, applied for an injunction against the Copperopolis people, and planted a suit for ore extracted from their ground in the sum of \$200,000.

WASHINGTON.

MINES AT BOUNDARY.—The Columbia Consolidated Mining Company, composed largely of citizens of Spokane, has transferred to Parker & Leavenworth of Seattle, the agents of an Eastern syndicate, its \$125,000 treasury stock, in consideration of which Parker & Leavenworth have agreed to build a canal, starting at the forks of the Cedar creeks, and to extend far enough to supply water to enable the Columbia Company to thoroughly placer mine their entire 800 acres of land, which huge the Pend d'Oreille and Columbia rivers. It is estimated by the Company's engineer that this canal will cost about \$35,000 in excavation, pipe, machinery, etc.

The Civil Service Gold Mining Company, organized and incorporated under the laws of the State of Washington, with a capital stock of \$100,000, and which is composed of capitalists of Washington, Montana, South Dakota, Kansas and Kentucky, has opened its main office in the Chamber of Commerce and Mining Exchange building at Boundary. The company controls the Margaret, Sarah C, Golden Treasury, Rosebud, Willie M, Mikado, Hattie, Madre d'Oro and Gold Rock.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the **MINING AND SCIENTIFIC PRESS**. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

WARNING.

Many so-called gasoline engines are now on the market which are direct infringements on our patents and it is our intention to bring suit against the various infringers. As the law holds the purchaser, as well as the manufacturer, we would advise parties who have already purchased other gasoline engines to obtain from the sellers of such engines **A GOOD AND SUFFICIENT BOND PROTECTING THEMSELVES IN CASE DAMAGES ARE OBTAINED AGAINST THEM**, as it is not the policy of this company to work a hardship on innocent parties, but the law makes no such provision.

Automatic Cut-off Steam Engine.

On this page is an illustration of a single valve cross-compound automatic cut-off steam engine patented and manufactured by Byron Jackson of this city. It is cast on a sub-base, high enough to clear the belt wheels from the floor. One wheel is left out of the cut to show the engine better. The engine can be changed from condensing to non-condensing, though it is as well to add the expense of a condenser.

A notable difference between this and other compound engines is the absence of any kind of extra pipes, passageways or receivers between the cylinders. Ordinarily it has been thought necessary to have an extra pipe or passageway of some kind through which the steam must travel from one end of the small cylinder to the opposite of the large cylinder; and when the communication is open at the end of the stroke, the steam passing from the small cylinder has to expand and fill the passageway or receiver before it enters the large cylinder; and if this passageway or receiver be large, the steam suffers a reduction of pressure which may be so great as to partially neutralize the gain by expansion.

In the engine illustrated there is no extra receiver, no extra pipe or passageway of any kind. The live steam enters the small cylinder, passes through the post and valve chamber into the low-pressure cylinder, and thence into the valve-chamber through the center of the valve to the exhaust at the end of the valve-chamber. This exhaust may be piped away from either end of the valve-chest as convenience requires, being usually connected at the front end under the engine, leaving the back end of the engine clear and readily accessible to the valve and pistons without removing any pipes. The valve being located below drains all condensed water from the cylinders. It is claimed that the engine having steam furnished from a plain horizontal tubular boiler properly set and properly fired will not consume over two pounds of combustible per indicated horse-power per hour.

THE situation in the Cripple Creek, Col., gold district is a deplorable one. The mines are held by men who do not own them but who threaten to injure the works and attack any and all who seek to get possession of their own property. The tone of the Colorado papers is that the miners are in the right. This view is probably due to their surroundings. The broad fact remains that any man has a right to do as he pleases so long as he interferes with no one else's right to do as he pleases. That is liberty. Anything else is either despotism or anarchy, and there is little choice between them. Doubtless the miners at Cripple Creek have their rights and their

wrongs, but their methods cannot be endorsed. They are opposed to American principles, and, like the disturbances among the Pennsylvania and Ohio coal miners, are the bitter fruit of blossoms blown to us from across the sea.

FAILING health is given out as Major Powell's reason for retirement from the position of Chief of the United States Geological Survey. Mr. Chas. D. Walcott, Chief Geologist, succeeds him. The intimate relationship between the position and public mining and irrigation interests makes the matter an important one. He is reported to have said that he will conduct the work along the lines

Gold Production.

Current statistics of the country's gold product in '93 estimate it approximating \$36,000,000—\$3,000,000 more than '92. The silver product for '93 is estimated at a little over \$78,000,000—a decrease of \$6,000,000 from the previous year. The returns published in these columns last week show the yield of gold in Australasia for '93 to be 1,876,561 ounces. Giving this a value of \$20 an ounce would make that worth \$37,531,240. It will be observed that Australasia produced more gold last year than the United States. For the first three months of '94 the Wit-

watersrand district in South Africa has produced 467,056 ounces, an increase of nearly 50 per cent over last year. The South African gold, so reputed, is about 0.82 fine. If the African output is kept up during the year the total will be about that of the United States for the same period. The average annual gold yield of the world for the last ten years has been \$32,000,000.

THE London Mining Journal proposes to solve the silver question by stopping all mining of silver and producing gold in such quantities that there would be an "over-production" of the yellow metal, thus enhancing the price of silver. It says "the remedy is transparent." It certainly does seem decidedly "transparent."

GOLD exports still continue in millions. Several causes are assigned—realization on American securities; "the balance of

trade"; money in better demand in Europe than here; light supply of commercial bills against exports of products to Europe, etc. 'Tis thought the tide will turn in the early fall and flow the other way.

The phenomenon known as "electric sunstroke" is now attracting special attention by reason of its frequency among workmen employed in melting metals by means of the electric process. The intense voltaic arc between the carbon and the metal to be melted emits rays, producing a sensation similar to that of a burn on uncovered portions of the body. There is frequently great pain, sleeplessness and in some cases fever. The skin becomes copper-colored or bronzed, the eyesight is sometimes temporarily lost and followed by what is known as "yellow vision," with a sensation as of sand under the eyelids.

FIVE DOLLARS a day is the quoted wages paid deputies in the Cripple Creek, Col., district. This is a great depreciation from the old days in Pioche, Nev., when no fighter would take hold for less than twenty dollars a day "and expenses." Probably the same relation exists as to the value of the service rendered.

JACKSON'S SINGLE VALVE CROSS-COMPOUND AUTOMATIC CUT-OFF ENGINE.

laid down by Major Powell. That gentleman's policy, while positive, was not at all times deemed progressive or satisfactory by those whose interests were involved, and it is possible that a modification of the late Chief's views would be in line with speedy and satisfactory settlement of important questions involved in the development of our natural resources.

CONSIDERABLE stir is being made over the inroads that electrolysis is making in the gas and water mains of this city. It transpires that by reason of lack of return wires on some of the electric street railways there is occasioned electrolytic corrosion of gas and water pipes. Though treated sensationally and exaggerated in some of the newspapers, it is evident that in several cases where the trolley system is used, the condition of pipes in the vicinity shows the necessity of guarding against electrolysis.

LAST week the city of Boston placed a loan of \$500,000 for a period of ten years at two per cent per annum. The State of Massachusetts has sold \$500,000 bonds drawing three and one-half per cent at 109. In Chicago call loans can be had at two per cent.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Jackson's Single Valve Cross-Compound Automatic Cut-off Engine, 337. Hotel Rubio, Mt. Lowe Railway, 342. Great Cable Incline of Mt. Lowe Railway; Glen Canyon, near Echo Mountain, 343.
 EDITORIALS.—Automatic Cut-off Steam Engine; Gold Production; Miscellaneous, 337. A Notable Decision; Salmon River Mines; Theories About Formation of Gold Nuggets, 338.
 CORRESPONDENCE.—Loss of Gold in Milling Ore, 339.
 SCIENTIFIC PROGRESS.—To Protect Boiler Interiors; Harnessing Electricity to Light; Items, 344.
 MECHANICAL PROGRESS.—The Age of Steel; Paper Pulp from Logs; Heating Iron in Water; Engineering Skill, 345.
 BOEOTRIC PROGRESS.—Possibilities of the Telephone; Uses for Vagrant Electricity; Electrical Dangers; Mechanical Force Derived Directly from Coal; Branding by Electricity; Items, 346.
 PRACTICAL INFORMATION.—Rosin in Beer Kegs, 346. Acreage Under Cultivation; How to Make Whisky; A Good Point About Cable Cars; Items, 347.
 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 351.
 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 349-350.
 MISCELLANEOUS.—General Mining Notes; General News Notes; Personal, 339. A New Pincer Machine; British Columbia Gold; As Explained by M. Josephson; Smelter for the Needles; Valuable Mineral Discovery; An Export Tax on Gold; Big Money in Amherst, 340. The Mineral Hydrocarbons; A Doubtful Experiment, 341. The Allotment of Gold; Indian Currency and the Far East, 342. Mount Lowe Railway; Pocket Mining; Glen Canyon near Echo Mountain, 343. The Advantages of an Earth Battery, 350. Coast Industrial Notes, 351.

A Notable Decision.

A decision of great importance to the mining interests of the west half of America was made by the Supreme Court of the United States this week. The case was Barden, et al., vs. the Northern Pacific Railway Company, and was decided against the company. It involves millions of dollars, and the verdict is in accordance with law, justice and equity.

The Northern Pacific's land grant was practically forty square miles for each mile of road built. Barden and associates discovered silver on a tract included in the railroad land grant and brought suit, the case being a test one. The railway people held that while they might be deprived of any part of their grant on which gold, silver, lead or copper was known to exist at the time the grant was made by the United States patent, that any subsequent discovery of metal could not affect their title to that or any portion of the grant. The plaintiffs pointed to the act itself granting the land, and after the usual interminable delay the case reached the highest court in the land, where it has just been decided (Justice Field of this State delivering the opinion), that the original exception of mineral lands at the time the Government made the grant was without any qualification, and that in giving that land to the railroad company all mineral lands, known or unknown, were specifically reserved to the United States.

It is a great victory for the miners. The thing is settled. There is no appeal, and hereafter, within the limits of the Northern Pacific Railway grant, or any other railway grant in the country where gold, silver, etc., is found, miners can acquire title to such land in the ordinary way undisturbed by tedious and costly litigation. The far-reaching consequences of the decision of the Supreme Court are manifest. It is of immense value to our mining interests and in every way satisfactory.

Now that this point is settled and settled right, it is in order to have an act passed by Congress setting forth exactly what "mineral land" is, in plainer and more precise terms than those of the present statute, so that the last faint possibility of future dispute may vanish.

The Dixon-Hartman bill is now on the House calendar, having been reported favorably by the House Committee on Public Lands, and has been held back by its friends awaiting the fate of the suit just decided in favor of the miners. This bill provides for the classification and segregation of mineral lands within railroad grant limits, and provides means for restoring such lands to the public domain. The passage of that bill is now believed to be certain. Of course there will be contests in the future, but in such future litigation it will not be the individual against the railway company; it will be the railway company against the Government.

The opinion was not a unanimous one; Justices Brewer, Gray and Shiras dissented.

Salmon River Mines.

Salmon River district, the southwestern portion of Siskiyou county, is a promising field for both the mining investor and prospector. The placer deposits of its river beds and bars early attracted a considerable population and have been moderately productive for nearly 40 years, and still remain so. At the present time the yield is principally from high bars and benches to which water has been brought by ditches often at a considerable outlay of time and money. These deposits, though not extensive when compared with the immense masses of auriferous gravels of the western slope of the Sierra Nevada, are amply rich enough to repay the investment of capital. At the head of the South Fork of the Salmon at Summerville the benches and bars paid well by hydraulicking for many years, and have only in the last two years been worked out and abandoned. The extension of the ditches used to supply water at Summerville will provide a water supply for a number of similar deposits farther down the river at Cecilville. Still lower down, at the mouth of Knownothing creek, the Red Point mine, a high bench deposit, is being hydraulicked very profitably. On the North Fork of Salmon river, at the mouth of Russian creek and above, are some extensive bench deposits that are as yet untouched, only awaiting the bringing in of a water supply. These deposits have been thoroughly prospected and will pay well hydraulicked. The water supply of the North Fork is available with a short line of ditch, so no large investment of capital is required. Elsewhere on the North Fork, and on the main river below the junction of the Forks, are several other hydraulic properties that will justify working on a much more extensive scale than at present.

The permanent promise of the district is, however, in the development of its quartz-mining industry. This is yet in its infancy, despite the extensive exploitation of a few mines that have made more than a local reputation. The entire drainage area of the Salmon does not contain gold-bearing quartz veins, as might be inferred from the distribution of the placer deposits. The limits of the gold-bearing quartz districts are fairly well known already, though there has been no such thorough prospecting as is the case with the quartz districts in the Sierra Nevada counties. In the Salmon river country the surface is steep, generally brush and timber covered, and the surface rock so broken up that the discovery of a quartz ledge in place as a rule requires stripping and trenching, following float and panning tests. The last are not easily made, owing to the scarcity of water. Such discoveries as have been made during the last few years have been the result of a systematic search, often on ground supposedly well known and over which hundreds of miners have passed, making more or less superficial examinations. A persistence in systematic prospecting is sure to result in the development of more valuable properties. For this, Sawyer's Bar is the best center of operations. Eddy's Gulch, White Gulch and the head of the North Fork of the Salmon north of Tanner's Peak, particularly the two last, are localities justifying, on the prospects already obtained, an investigation extending over years and involving considerable expenditures. From White's Gulch and the head of the North Fork of the Salmon the large amounts of gold mined out of the bars and benches of the North Fork above Sawyer's Bar must originally have come. There are no blue leads or old channels to feed these deposits. As a fact, however, the ledges from which the gold came, excepting a few discoveries in White's Gulch, have not been found. They are certainly worth hunting for. As a whole, the record of the quartz mines of the Salmon river country has been good. Profitable mining has been the rule. In Knownothing creek district all the discoveries have been made since 1886. The Hansen mine, the Knownothing, and the Gold Run group, the only mines worked, have all been profitable properties. The only one of these mined extensively, the Gold Run, has made a steady improvement with depth. Starting at the surface a narrow chute of ore in a ledge that hardly seemed in place, the chute has steadily lengthened from 20 feet till at a depth of 500 feet it is 150 feet. With increased depth, spurs and parallel veins have been cut in the working tunnels, each rivaling in extent and richness the original pay chute. With a yield to date close up to \$150,000, there is at the present time more than that sum in sight in the mine. The average yield of the ore milled for two years past has been over \$50 a ton. The Hansen mine is another almost equally promising property. Mined down to the water level through tunnels, considerable high-grade ore has been taken out. The extent of the development warrants a hoisting and pumping plant capable of opening the mine to a considerable depth. There is reason to anticipate the development of much larger ore bodies with depth. In the vicinity of these mines and in the country extending southwesterly toward the New

river district in Trinity county there is an opening for prospectors. It is probable that a systematic exploration would develop a number of valuable mines.

Black Bear district, at the head of Black Bear creek and including Eddy's gulch, is the oldest and best developed quartz locality in the Salmon river country. The Black Bear mine has a record of yield of over a million and three-quarters to its credit, and is a promising mine to-day. New ground has been discovered above the tunnel level, and is being developed for working on a large scale. Other mines—the Klamath, Gold Ball, Fagundez and Uncle Sam have all been profitable properties, though at times having their period of depression when they didn't pay. It is, however, a conspicuous fact that in the long run all of the mines show a considerable profit balance. It is this feature which should encourage investment of capital and extended prospecting. For only the last two years has there been a wagon road into this country. Its isolation and lack of communication have operated to retard its development, even though it had a conspicuous advertisement in the Black Bear mine. None of the mining or milling plants are of approved modern construction, and the cost of operation has been higher and the percentage of the gold in the ore obtained smaller than should be the case. The construction of the road makes it possible now to bring in heavy machinery at a moderate cost, comparatively, and to do cheaper and better work.

Theories About Formation of Gold Nuggets.

By George Attwood, F. G. S., Assoc. Inst. C. E., M. Am. Inst. M. E.

Recent articles in these columns regarding the formation of gold nuggets, do they grow and how they grow, etc., have elicited some discussion. The following article has been furnished as a contribution to the current topic:

In the State of Guyana, Venezuela, South America, a large area of alluvial soil has lately been found to contain gold in paying quantities, and nuggets of 25 ounces in weight have been discovered within three feet of the surface.

The gold deposits are situated in a district called La Pastora, and in about latitude 7° 25' N. and longitude 62° 10' W. Numerous quartz veins are found in the neighboring hills, all of which contain more or less gold. The soil is dug up, carried on donkeys to the nearest supply of water, and then washed by the miners in a wooden bowl called a "batea."

The coarse gold is easily saved; the fine is separated in the form of an amalgam by the previous addition of a little mercury in the "batea."

Upon personal examination I found that fully one-half of the gold nuggets which were produced in this district were covered with a dark-brown substance resembling a silicate of iron. I also found it customary among the miners to beat the nuggets on a blacksmith's anvil (or with two hammers) to clean them before selling to the local merchants. A nugget which had not been hammered was selected by myself, and, after examination, it afforded the following results:

Weight.....75.00 grains
 Weight after fusion with borax.....65.56 grains

Loss in melting=12.58 per cent..... 9.44 grains

The nugget was in places covered with earthy matter, which would account for the loss in melting. The fused nugget was now assayed and gave:

Gold.....931.4
 Silver.....068.4

Total.....999.8

A nugget nearly covered with glazed ferruginous earth was now examined:

Weight before treatment.....304.70 grains
 Weight after treatment with HCl and NaO.....284.33 grains

The nugget, after being attacked with HCl, the following ingredients were found soluble:

Silica.....0.12 grains
 Fe₂O₃.....8.88 "
 CaO.....0.15 "
 MgO.....0.08 "

Total.....9.23 grains

The nugget was then treated with NaO, and afterward with HCl, and the following ingredients were found in solution:

Silica.....4.66 grains
 Fe₂O₃.....4.60 "
 CaO.....0.21 "
 MgO.....

Total.....9.47 grains

The gangue on the surface of the nugget weighed 20.37 grains, and 18.70 grains were accounted for in the treatment by HCl and NaO, leaving a loss of 1.67 grains. The loss is probably owing to the presence of hydrated oxides of iron.

After the nugget was boiled in HCl a quantity of fine flour gold, resembling freshly precipitated gold, was found

and collected. Having every appearance of being pure, it was carefully tested; but it was found to contain silver similar to the solid portion of the nugget. A large portion of the nugget's surface, after treatment with HCl and NaO, presented a peculiar appearance, and was found to be partly covered with a coating of fine gold of a dull color, and which, upon scratching or shaking violently, became detached from the more solid mass.

A portion of the cleaned nugget was fused with borax—

Weight.....	93.14 grains before fusion.
.....	92.50 " " after " "

Loss.....00.64 grains; = 0.68 per cent.

It was then assayed and found to contain—

Gold.....	945.4
Silver.....	654.4

Total.....999.8

As a comparative test of the difference in the composition of the gold obtained from the quartz veins and that found in the alluvial soil, a small quantity of gold amalgam was obtained from the Potosi Mining Company's crushing mill, and it contained as follows:

Mercury.....	55.55 per cent.
Copper.....	1.79 " " = 4.03 per cent in retorted gold.
Silver.....	3.57 " " = 8.62 " " " "
Iron (trace)...	
Gold.....	39.08 " " = 879.40 " " " "

In the analysis of the amalgam, the fineness of the gold appears less than it is when shipped for market, as the amalgam undergoes a cleaning treatment before melting; also in the fusion the gold is again purified, so that the average assays of a large quantity of gold have shipped from this district has ranged from 910 to 925 in fineness. The gold obtained from working the quartz veins is always of a baser character than that obtained from alluvial washings.

In conclusion: From the above experiments, made and recorded on a gold nugget covered with a glazed ferruginous earth, it would appear to me to prove that gold nuggets do gradually increase in size, owing to the accumulation of fresh particles of finely precipitated gold.

General News Notes.

The late W. T. Coleman left a \$425,000 estate.

The Midwinter Fair closes four weeks from to-day.

The Smuggler, at Aspen, Colo., is reported to be earning \$50,000 monthly.

C. P. HUNTINGTON has purchased a controlling interest in the Piedras Negras coal mines in Coahuila.

COLONEL R. S. BAKER, a California pioneer, after whom the town of Bakersfield was named, died at Los Angeles on Saturday at the age of sixty-nine years.

The Holden chlorination plant at Cripple Creek is reported to be successfully treating the ores of that district. The plant is handling 20 tons of ore per day at a cost to the miner of \$12 per ton.

GEN. JOHN HEWSTON, a well-known Californian, is arrested in London, charged with killing one of a party of musicians who molested him on the road. Hewston struck him with his umbrella, with fatal effect.

From January 1st to May 1st the specie imports into San Francisco by water amounted to \$1,063,159, about one-third being gold. Of the aggregate, about one-half came from Mexico, one-fourth from Australia, the remainder from British Columbia, Central and South America.

TREASURER E. E. STARR paid \$6,840,000 to 24,300 Cherokee Indians at Tahlequah this week, the proceeds of the sale of the Cherokee Strip to the United States. Every Cherokee Indian has bought a Winchester rifle and two or three revolvers, and there is promised considerable hilarity on the back seats.

The New York and Chance mine of Creede has shipped 50 tons of ore to the Ontario mill, Park City, Utah, to be treated by the amalgamation process. If the experiment proves successful, says *Ores and Metals*, the New York and Chance Company will put up a \$100,000 plant at Creede with a capacity of 50 tons per day.

ENGLISH and American statesmen are giving England instructions as to her duty and best policy in the present silver crisis. India and the Argentine Government are doing the same thing in a more direct way. The first necessity appears to be to acknowledge a mistake was made. Till such acknowledgment the matter must stand as it is.

NORTHERN FLOODS are wreaking havoc. In British Columbia the entire Fraser River valley is inundated. In northwestern Washington, floods have swept everything, the town of Concomully being entirely washed away. Much damage is also reported on the upper and middle Columbia. The rivers have all attained the highest point in memory.

CRIPPLE CREEK, Colo., and vicinity is on a war footing. The striking miners have fortified themselves, placed dynamite in several mines and works and declared defiance. The mine-owners decline to yield, and all efforts at arbitration are futile. About 2000 men hold the mines against their owners, and Gov. Waite, weak and wobbly, while supposed to favor the strikers, is trying to turn events to popularize himself.

Personal.

PROF. N. S. KEITH is now in Chester, England, and is reported successful in introducing electric machinery in English mines.

JAS. PENNEROAST died in this city last Sunday. He was a resident of California for thirty years, and was one of the founders of the Etna Iron Works.

General Mining Notes.

THE Hillside, Arizona, gold mine, formerly a great producer, is being reopened.

THE Elkon Mining Co. of Colorado recently paid a dividend of one cent per share, amounting to \$5000.

THE Homestake Mining Co. of South Dakota paid a dividend of 15 cents per share, or \$18,750, last week.

THE Copper Queen Mining Co. of Arizona has paid a dividend of 25 cents per share, amounting to \$500,000.

PRESIDENT CLEVELAND is reported to have bought a one-half interest in the Caledonia mine at Cripple Creek, Col.

THIRTY-SIX bars of silver bullion, 99 per cent fine and weighing 80 pounds each, were shipped from Butte, Montana, for Europe this week.

HENRY CAMPBELL and John Gilderslave, at work in a placer mine on Cave creek, Oregon, were killed on the 25th ult., by rocks falling on them.

THE quicksilver mines on the Hassayampa, below Wickenburg, Arizona, is being developed by the owners. Kansas City capital is interested in the enterprise.

THE *Transcript* says that W. F. Derham, who won the first prize in the single-hand drilling match at San Francisco Tuesday, is a resident of Nevada City.

THE Ella Heelan Gold Mining Company have a franchise to mine under the streets and alleys of Cripple Creek, Col., as soon as existing labor troubles are over in that lively locality.

According to the London *Mining Journal* of May 12th, the total yield of gold for the month of March, 1894, in the Witwatersrand, South Africa, district was 165,372 ounces, valued at \$569,295.

H. H. ST. JOHN, of Spokane, Wash., has sold his one-third interest in the Idaho mine, Slocan district, to N. D. Moore, a Duluth capitalist, for \$17,000. This is at the rate of \$51,000 for the entire property.

SUPERINTENDENT BROCKINGTON tells the Grass Valley *Union* that the Orleans Company will start at once to erect a new five-stamp mill. A contract was awarded McPhear & Co. to sink the shaft sixty feet.

THE Lincoln Gold Mining and Milling Co. of Placer county has incorporated. Directors—Fred C. Crosby, George S. Williamson, William K. Flint, S. B. Moore and F. H. Hansman. Capital stock, \$500,000.

THE *Record* says a company made up of Denver men is investigating a proposition to build a stamp mill of 100 stamps and a concentrating process with it, to work the ores of Gilpin and Clear Creek counties.

FROM Boise, Idaho, come reports of an excitement over alleged rich placer diggings in the southern part of Idaho county. Men are reported to be taking out \$100 a day with a rocker, but the report lacks verification.

THE Sierra Buttes Gold Mining Co., and the Plumas Eureka, owning the two mines named in Plumas county, at a recent meeting in London declared a dividend of 12 cents a share on the former and 18 cents on the latter.

THE Wahsatch, Utah, *Wave* says there is considerable excitement over the discovery of gold in Deer Creek canyon, lying just at the head of Provo canyon and to the west of it. Assays have been had ranging from \$7.22 to \$12 per ton in gold.

It is reported that a Denver syndicate has offered Mr. Thomas Lowthian \$400,000 for his Lone Star mine at Cochiti. As there is about four times this much ore in sight on the claim, the offer was refused, of course, says the *Santa Fe New Mexican*.

THE California Gold Mining and Investment Co. has filed articles of incorporation in Plumas county. Its principal office is at Helena, Montana. The capital stock is \$1,000,000. The idea is to work the "Taylor Diggins," near Genesee valley, Plumas county.

A CORRESPONDENT writing from Champie's camp to the Phoenix, Arizona, *Gazette* says that a good custom mill, equipped with concentrators, would pay handsomely at that place. At present the ores of the district are reduced by the tedious process of arrastras.

THE new converter plant at the Anaconda plant in Montana is in operation. It has a working capacity of 10,000,000 pounds of pure copper per month. It is built entirely of iron, extending 380 feet long and 124 feet wide, containing 24 converters and giving employment to 124 men.

THE Grass Valley *Tidings* says a new air compressor is now on the way for the W. Y. O. D. mine, and Superintendent Weissbein expects to have it running inside of three weeks. Five drilling machines are to be placed in the mine, and will be used in sinking the shaft and in running drifts.

THE Copper Queen mine, says a Bisbee (Ariz.) correspondent, is the largest producer in the world of like ore, and there is enough copper in sight, without further investigation, to keep 600 men busy for 12 years longer. They have the adjacent mountains prospected and have found them laden with precious metal. Here are 22 nationalities, 15 different religious beliefs.

By a recent cave-in at the bluffs at Tacoma, Wash., Major W. T. Gillespie, a well-known Utah mining man, and Arnold Barrenberg, an engineer, were killed and two workmen injured. Gillespie was superintending the slicing down of a section of the bluffs, where the hydraulic pump was in use, when the accident occurred.

JOE. ROUSE, who recently died at Lovelock, Nevada, at the age of 74, was a celebrated character in the early days of Nevada when "feet" in mining claims were a legal tender. About the time that "feet" were demonetized he was amalgamator in the Pioneer mill, the first quartz mill in Nevada east of the Comstock. He was an old-time prospector and had extensive acquaintance all over the coast.

In accord with a similar decision by the Supreme Court of this State several years ago, the United States Supreme Court has decided that no railroad company can claim in its land grant any tract containing mineral. The Northern Pacific Railroad Co. claimed a tract within the limits of its Government grant on which gold had been discovered, and the Su-

preme Court declares that the miner can secure title for such tract from the Government direct, and that the railroad company has no claim in the matter.

THE new Elk Creek district, on the South Platte, 40 miles from Denver, is reported to have shipped a ton of ore to Denver which is currently reported to have yielded over \$170 per ton in gold. The ore is an iron and copper pyrites. The veins are found in granite. The deepest hole in camp is only 20 feet.

DURING last April the United States produced 27,046,296 pounds of copper, being 4,152,462 pounds more than this country's quota under the tacit international agreement. During the same time foreign mines produced 16,542,400 pounds, 664,280 pounds in excess of their allotment. Decreased exports from this country are viewed as an evidence of increased home consumption, and consequent higher prices.

MICHAEL GILMORE was killed near Butte, Montana, by Andrew Erichs in a dispute over a mining claim last Saturday. Gilmore, during Erichs' absence, jumped a valuable placer mining claim belonging to Erichs. Erichs returned and demanded possession. Gilmore refused and opened fire, but missed, and Erichs emptied the contents of a double-barreled shotgun into Gilmore, killing him instantly.

BUT little is at present being done in the matter of applications to the Debris Commission for permits for hydraulic mining under the provisions of the Caminetti law. Two applications—one from the Concordia, the other from the Northern Placer in Plumas county—have been received during the last two weeks. Later in the year there will probably be more activity in that direction. Permits have been issued to the owners of the Excelsior, Craycroft Hill and Eureka near Downieville, making a total of forty-one since its organization.

FERNAND FARMHALLS has sued the estate of John Roach for \$50,651.72. The suit is based on the sale by Roach of plaintiff's one-quarter interest in the Abbott quicksilver mine in Lake county. The sale was made in 1876 and Farmhalls then received \$1870, which amount he was told by Roach was all that had been received. He now alleges that Roach in fact received \$22,000, all of which he fraudulently appropriated to his own use, except the \$1870, for which he accounted to his principal. Farmhalls' present claim is for the balance due, with interest from March 8, 1874.

FOUR men have arrived at Revelstoke from French creek, in the upper Big Bend. George Laforme brought \$2100 in coarse gold and nuggets from the Consolation mine, of which he is one of the four owners. This represents four week's work for four men. The mine has turned out on an average \$1000 a month for the past ten months. The bag weighed over ten pounds, and with some gold added, which brought the amount to \$2550, and weighing over eleven pounds, was sealed and sent to this city for sale, the banks here giving 50 cents an ounce more than can be obtained in British Columbia.

R. H. BLIVEN of Loomis, Wash., claims to have perfected a gold-saving device that is cheap and satisfactory in cases of refractory ores. He naturally declines to name his compounds, but gives the method in general as, "A lixiviation or leaching process, in which a chemical solution having energetic solvent powers for gold, iron or copper, but rendering lead, antimony and silver insoluble, is leached through the fine ore pulp in tanks. After settling, the clear solution is drawn off and the gold precipitated by a simple and cheap precipitant that throws down only the gold, separating it from the other metals."

THE Arizona *Journal-Miners* says: The financial troubles of the Henrietta Mining Company still remain unsettled. They are said to have been caused through an agreement to apply 50 per cent of all the bullion taken out on the payment of the mine, and there is scarcely a mine in the world that would permit of 50 per cent of its gross receipts being taken out and then have sufficient left to pay for mining and milling the ore and for development work in the mine. The employees of the mine are said to be in possession of the last cleanup of bullion, amounting to \$2000 or less, which they are holding until they receive their pay for work.

AT the Ontario mine, Park City, Utah, says the *Record*, the amalgamating plant is used for the treatment of silver ores carrying 50 ounces per ton or less. The highest grade ores are sent to the smelters. The cost ranges from \$2 to \$4 per ton, and from 85 to 95 per cent of the assay value is saved. At the Daly mine, in the same camp, the Russell leaching process is used. This claims to get even better results than amalgamation and at lower cost. Be this as it may, the Ontario mill is one of the best in the country. Its success is to be tried on the Creede low-grade silver ores, and if found successful will revolutionize the present method of treating this product.

S. R. COX, who was at work at the Winder mine, located 12 miles from Barstow, fell down the shaft on the 20th ult., catching on the projecting timbers which knocked him senseless. C. C. Kehr, who was working with him, lowered him to the ground and went for help. In his absence Cox came to and started to climb up the ladder. His strength gave way and he fell again, crushing his right cheek bone and tearing off his eyelid, which was found on the projecting timbers. Cox started up the ladder a second time, and was found dead about 25 feet from the bottom, clinging to the rounds of the ladder. Cox was about 55 years of age, and had been in the district only a few days.

ON Thursday the vote on the best county mineral exhibit at the Midwinter Fair stood as follows: Nevada 388,096, El Dorado 260,208, Placer 95,699, Amador 68,452, Tuolumne 33,458, Calaveras 22,141, Plumas 16,875, Trinity 15,029, Sonoma 15,013, Shasta 8385, Butte 7193, Sierra 5382, San Benito 5313, Tulare 4386, Santa Cruz 4226, Santa Clara 3899, Alameda 3712, Mariposa 2999, Mono 2774, Lake 2637, Napa 2615, Kern 2042, Fresno 1978, Siskiyou 1690, Santa Barbara 1651, Riverside 1546, Kings 1528, Ventura 1461, San Bernardino 1439, San Mateo 1376, Sacramento 1125, Los Angeles 1118, San Joaquin 1013, San Luis Obispo 923, Alpine 926, Humboldt 844, Yuba 805, Tehama 744, Solano 527, San Diego 463, Modoc 419, Inyo 285, Del Norte 264, San Francisco 202, Colusa 176, Lassen 116, Contra Costa 116, Marin 78, Sutter 66, Merced 65, Orange 60, Monterey 58, Glenn 44, Madera 41, Mendocino 20, Yolo 18, Stanislaus 16. The vote determines nothing beyond the "rustling" ability of the friends of the various county exhibits and cannot be cited as proof *per se* of the merit of any particular exhibit.

Loss of Gold in Milling Ore.

TO THE EDITOR:—I have just been reading a letter under the above heading by Mr. G. F. Deetken in your issue of the 19th inst. Like a good Californian he incidentally attacks the Gilpin county (Colorado), milling practice and quotes Mr. Argall in support of his condemnation of methods so unlike those of California. Mr. Argall said that "the saving by amalgamation does not exceed 60 per cent on average ores." Mr. Deetken quotes him as having noted "a present loss of 40 per cent in milling in Gilpin county." A loss of 40 per cent "in milling" is very different from an equal loss "in amalgamation," for to the saving by amalgamation must be added the saving by concentration before you can figure out the saving or the loss by "milling." Concentration forms a very important feature of the Gilpin county method as in use to-day.

As the result of many years' experience of the work done at Black Hawk, I would consider Mr. Argall's estimate hardly fair. At any large, well-managed mill, supplied with the output of any particular mine, it is found that about as much gold is obtained in the mill as the fire assay shows. Now, the mill gold is about 760 to 780 fine, therefore the saving by amalgamation is close to 76 or 78 per cent.

At the custom mills and in the treatment of small lots of ore the results are not so good because the best conditions for successful work are not determined until the ore has been all or nearly all passed through the mill.

Mr. Argall says that his "experience is but that of an occasional customer of the mill." This fact may explain the difference in the estimates which we have formed.

T. A. RICKARD.

Denver, Col., May 23, '94.

A New Placer Machine.

A Denver, Colorado, mechanic has devised a new gold-saving device whereby he claims he can do, with currents of air and motion, what water and motion will do in a pan or sluice. The machine is a box, suspended at any desired angle in a frame, having a rapid side motion or shake. At the upper end of the box is a hopper, over which a screen is placed of any desired mesh. This screen has an outlet or spout. All dirt is thrown or deposited upon this screen. From the hopper beneath, the dirt is dropped or fed upon a rapidly-revolving spiked wheel. This wheel pulverizes and disintegrates the dirt. In front of this wheel is a stationary breaker, through and against which the dirt is thrown or driven. By these appliances the dirt is thoroughly broken and pulverized. The dirt then passes across an air chamber attached to the bottom of the box. Over the air chamber is a fine screen. A number of riffles are attached to this screen. Air is driven into the air chamber from a blower beneath.

The air, passing through the fine screen under the riffles and coming in contact with the dirt, combined with the rapid side motion, not only carries the dirt over the riffles, but causes the gold to be sifted to the bottom and retained in the riffles. Fans are attached to the spiked wheel beneath the hopper. The current of air created by these fans, passing down through the box, comes in contact with the current of air from beneath the box, in a hood or cover lined with carpet.

The hood has a returning and retaining board, to which a riffle is attached. This combination hood lined with carpet, is for the purpose of catching and retaining all microscopic gold. Below the air chamber, amalgamated plates and riffles are attached to the bottom of the box.

The device is known as the Gold King dry placer machine, being handled by a company of like name. They claim to be able to save from 90 to 100 per cent of gold values, from all kinds of sand, gravel, dried clay and reasonably moist dirt. These facts, they say, have been demonstrated by practical tests in the field.

British Columbia Gold.

The Fraser river excitement of 1857 is still remembered by some old Californians. The yield of gold in this State had begun to fall off, and many thought the mines would soon be exhausted. Reports of valuable discoveries along the Fraser river in British Columbia were received, and there was a general rush for the new diggings. Much San Francisco property was sold at very low prices by those who wished to try their luck at the north, and every berth in the steamers was taken for some weeks. Many of these adventurers were glad to beat their way back to California in a dilapidated condition, sadder and wiser. The event brought British Columbia into notice as a gold producer, and from that day to this some gold has been annually secured from her mines. The product for 1858 was \$520,357. In the following year it was \$1,615,000. For the next four years the annual average was \$2,285,200. In 1864,

the yield was \$3,735,851, the largest in the history of that district. The product has since steadily declined, though it was maintained at upwards of \$1,000,000 per annum to the close of 1881. For the next eight years it was from \$954,000 to \$588,800, and for the past four years from \$949,400 to \$379,500. From 1858 to 1893 inclusive the yield was \$53,892,997.—Bulletin.

As Explained by M. Josephson.

M. Josephson, who recently came hither from Cripple Creek, gives an account of the origin of the trouble to the *Report* as follows:

"When silver became demoralized," said Mr. Josephson, "a lot of silver miners were thrown out of employment, and they descended on Cripple Creek looking for work. The result was that the gold miners were thrown out of employment because the silver miners would work for less money than the gold miners would. The gold miners struck, but you heard very little about it because it was suppressed as news. That was last January. The gold miners soon saw they were not in it and they did not make much of a fight. They surrendered and got out and went to other places.

"Then the silver men had it all their own way for a while, till some economical mine owner thought of coal miners. He got others to join him, and as a result a lot of coal miners were imported to Cripple Creek from Trinidad and other places in southern Colorado and New Mexico. The coal miners would work for less than the silver miners and that is the key to the whole fight. The silver miners were notified they must accept coal miners' pay or lose their jobs, and they struck and there you are."

"But this matter of pay, Mr. Josephson—what does it amount to?"

"Well, the gold miners got about \$4.50 a day and every one was content. Silver miners get about \$3.50 a day and they cut the gold miners' throats to that extent when they went to Cripple Creek. For a time everything went along bloomingly at that rate, but when coal miners were introduced wages went still lower. Coal miners work at \$2.50 to \$2.75 a day. So you see the difference, and you see what the silver men are fighting about."

Smelter for the Needles.

There is no doubt that a smelter will be established at The Needles, according to General Manager Cahel, in an interview with the editor of the *Winslow Mail*. The company has been incorporated under the laws of Arizona, plans and specifications have been prepared, a site selected near the old bridge across the Colorado river, and within a few weeks, when another meeting of the directors will be held, contracts will be ratified and steps taken to inaugurate the work of construction. The plans contemplate the building of two furnaces of 100 tons capacity daily, two roasters with brick stays 5x5 ft. and 80 ft. in height, together with sampling works, necessary elevators, etc. The plant will cost \$100,000 in round numbers, two-thirds of which has already been subscribed. For a month past an agent has been at work securing estimates as to the amount of ore on which a smelter could rely, and it is found that at least 100 tons daily could be counted on at the start, 79 of which will come from the Prescott Hills, Vanderbilt and other camps. By the establishment of the smelter the road will secure ten cars of freight a day. Shippers of ores between Prescott, Arizona, and Mojave, California, will be given a lower rate by from \$4 to \$7 per ton than shippers at other points who send their ores to Colorado.

Valuable Mineral Discovery.

Professor Von Peterdorf has returned from a trip to the Tejon country, during which he made quite an extensive investigation of that part of the country, says the *Bakersfield Californian*. Among other things he discovered a large ledge of marble which is of good quality and promises to become of great value when properly developed. He also found ledges yielding zinc, iron, lead, copper, molybdenum and best of all, gold. The latter runs about \$50 to the ton. Out-croppings of coal of good quality have also been found by him at several points in the foothills.

The professor has just received a letter from the State University, whither he sent some of the large bones dug up some time ago by him and John Baker in the hills to the north of the Baker place. These bones, the University reports, are of some amphibious mammal of a species resembling the hippopotamus or tapir, and whose habitat was the shores of the great inland sea that once covered this valley. The animal was a vegetarian, and lived on the palms and other tropical growths which flourished here then—anywhere from ten thousand to ten million years ago. He was of immense size and was a fit companion for the stupendous animal growth of that period.

An Export Tax on Gold.

One of California's Congressmen is about to introduce a bill levying an export tax on gold in any form. His aim is to get the bill thoroughly discussed during the present session, but not to let it come to a vote. With the growth of popular opinion in favor of silver, he hopes either to pass the bill during the next session or use it as a strong lever in favor of monetizing silver.

"The idea of this movement," he says, "is simply to enable the United States to enjoy a part of the profits which England is getting from American securities owing to the debasement of silver. This country owes tremendous sums to British investors in the way of bonds. When the interest or principal on these is paid it must be handed over to the foreigners in gold.

"Gold here will buy no more than silver, but it goes a long way further than silver for the purposes of capitalists abroad. Of course there is no new information in that, but the purpose of my bill is to cause English profits to be expended here for commodities other than gold. Inasmuch as the former can be sent abroad without export duty while the English will have to pay us a heavy percentage on all the yellow metal they ship over the Atlantic, I believe that it only needs some firm action of this country in order to bring England around to a silver basis, and I propose to do what I can to bring such action to pass."

In support of the latter statement, he produced a copy of an editorial recently printed in the *London Financial News*, a portion of which reads as follows: "Senator Cameron points a plain moral when he remarks that if the United States would venture to cut herself adrift from Europe and take outright to silver, she would have all America and Asia at her back and would command the markets of both continents. The barrier of gold would be more fatal than any barrier of the Custom-house. The bond of silver would be stronger than any bond of free trade. There can be no doubt about it, that if the United States were to adopt a silver basis to-morrow British trade would be ruined before the year was out. Every American industry would be protected not only at home but in every other market.

"Of course, the United States would suffer to a certain extent through having to pay her obligations abroad in gold, but the loss on exchange under this head would be a mere drop in the bucket compared with the profits to be reaped from the markets of South America and Asia, to say nothing of Europe. The marvel is that the United States has not long ago seized the opportunity, and but for the belief that the way of England is necessarily the way to commercial success and prosperity, undoubtedly it would have been done long ago.

"Now, Americans are awakening to the fact that so long as they narrow their ambition to becoming larger than England they can't beat us. It has been a piece of luck for us that it has never before occurred to Americans to scoop us out of the world's markets by going on a silver basis, and it might serve us right if, irritated by the contemptuous apathy of our Government to the gravity of the silver problem, Americans retaliate by freezing out gold. It could easily be done.

"We propose shortly to show, by evidence collected from perfectly unprejudiced sources, that even now the process has begun, and is proceeding at a rate that will astonish most people, and probably make this country regret that it did not at an earlier stage fashion its monetary policy on principles of friendliness to other nations instead of on a basis of short-sighted selfishness."

Big Money in Ambergris.

Says the *Sydney Bulletin*: Apropos the whales disporting outside Sydney heads recently. Two years ago one of Macgregor's (Tasmania) whaling captains, having cut the blubber from a whale, was about to cast the rest of it adrift, when there came alongside two Hobart fishermen—"Portuguese Joe" and his mate, an African negro. The Portuguese begged to be given the carcass, so that they might tow it ashore and make what they could out of it. "All right," said the skipper, with the generosity of a satisfied exploiter who knew the blubber business to its omega. Joe, having got the leviathan's framework on the beach, began to search for ambergris, which drug was quoted at that time in the current price lists at somewhere about \$65 per ounce. He found 174 pounds. Many people interviewed him, and wanted to give him \$25,000 to \$45,000 for the lot; but the man understood the luck of his find.

Meanwhile the ambergris was lodged in a bank, which was presently served with an injunction, on behalf of the Macgregor firm, to restrain the sale of the precious prize, pending a discussion on the ownership. But these legal fireworks fizzled out, and the ambergris is still being realized in London, the two fishermen having already received several thousand pounds apiece.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER 1.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894 by Henry G. Hanks, F. G. S.

Petroleum is one of the few minerals, if not the only one within the observation of man, which exists in the three forms of nature—solid, liquid and gaseous.

In this history the mineral hydrocarbons will be divided into three groups, those which are solid at ordinary temperatures, those which are liquid and those which are gaseous.

Under the first heading will be included asphaltum, mineral coal and numerous combustible minerals resembling both. The second class will be maltha, petroleum and naphtha, and the third natural gas.

Natural gas, naphtha, petroleum, maltha and asphaltum were doubtless known to man before the birth of history. The earliest records that survive the destroying hand of time refer to these natural substances and their limited use.

The word asphaltum appears at least five times in the Bible under the name of pitch and slime. (Genesis 6-14; 11-13; and 14-16. Exodus 2-3; and Isaiah 34-9).

Moses, the first known historian, describes in the first books of the Bible the deluge and the building of Noah's ark. "Make thee an ark of gopher wood; rooms shalt thou make in the ark and shalt pitch it within and without with pitch. * * * And when she could no longer hide it, she took for him an ark of bulrushes and daubed it with slime and pitch."

Asphaltum is also frequently mentioned by other ancient writers.

The cuneiform inscriptions of the East were known to moderns long before they could be deciphered. In 1842 certain mounds near the town of Mosul in Mesopotamia, Asiatic Turkey, opposite the ancient site of Nineveh, were opened and a multitude of baked clay tablets, some much broken, were found. These were sent mostly to the British museum, where they were studied and finally translated. It was then known that a similar account of the deluge was impressed on some of these tablets, and it was inferred that Moses and the unknown Assyrian or Chaldean historian had related the same story in similar words, presumably derived from a common source, and that the tablets possibly antedated the books of Genesis and Exodus.

The Babylonians and Assyrians were civilized nations something like 2000 years before the Christian era. It is now believed that in the Royal library at Nineveh there were 10,000 inscribed tablets on general literature and history.

On some of these tablets, bitumen is certainly several and perhaps many times mentioned. The following translation from the deluge tablets is given in "The Chaldean Account of Genesis" (George Smith, New York, 1870, fol. 266): "Three measures of bitumen I poured over the outside; three measures of bitumen I poured over the inside."

Berosus, a Chaldean historian who lived in the time of Alexander the Great, was no doubt familiar with the tablet literature of the period. He wrote a history of Babylonia and Chaldea, a portion of which is quoted by Alexander Polyhistor, a Greek historian, as follows:

"The ark was stranded in Armenia; some parts of it still remain in the Corycæan mountains and the people scrape off the bitumen with which it had been outwardly coated and make use of it by way of an alexipharmia and amulet."—(Cory's Ancient Fragments, fol. 63.) The author must have drawn heavily on his imagination, for Ararat is practically inaccessible, and it is not likely that "certain persons" would make frequent visits to the top of the mountain for any purpose.

Mount Ararat consists of two enormous conical masses of unequal height, rising from a plateau itself 300 feet above sea level; the highest summit rises to an elevation of 17,112 feet. In modern times a number of unsuccessful attempts were made to reach its summit before 1829, when it was climbed by Dr. Parrot, a German. Ascents have since been frequently made. The mountain is an extinct volcano.

Marco Polo (book 1, chapter 4), who visited China and the East in the 13th century, mentions this mountain in the following words: "In the central part of Armenia stands an exceedingly large and high mountain, upon which it is said the ark of Noah rested, and for this reason it is termed 'The Mountain of the Ark.' The circuit of its base cannot be compassed in less than two days. The ascent is impracticable on account of the snow toward the summit, which never melts but goes on increasing by each successive fall."

Theophrastus (History of Stones, chapter 24,) describes a stone believed by the translator to have been indurated asphaltum. "That also which is called 'spinus' is found

in the mines. This stone, cut to pieces and thrown together in a heap exposed to the sun, burns, and the more so if it be moistened or sprinkled with water." There is but little reason to believe that the author has described any form of bitumen. The described properties are those of lignite, which it probably was.

The following may be found in the writings of Pliny (Natural History, book 35, chapter 51).

"Nearly approaching the nature of sulphur is that of bitumen, which in some places assumes the form of a slime and in others that of an earth—a slime thrown up, as already stated, by a lake in Judea and an earth found in the vicinity of Sidon, a maritime town in Syria. In both these states it admits of being thickened and condensed. There is also a liquid bitumen, that of Zacynthus (the island of Zante) for instance, and the bitumen that is imported from Babylon, which last kind is also white. The bitumen, too, of Apollonia is liquid. All these kinds in Greek have the general name of 'pisasphaltos,' from their strong resemblance to a compound of pitch and bitumen. * * * Bitumen to be of good quality should be extremely brilliant, heavy and massive; it should also be moderately smooth, it being very much the practice to adulterate it with pitch. * * * It has already been stated that bitumen was formerly employed for staining copper and coating statues. * * * It has been, too, used as a substitute for lime. At the smithies they are in the habit of varnishing iron and the heads of nails with it, and of using it for many other purposes as well."

Diodorus Siculus (Book 4, Chap. 1) informs us that "among the Agyreans something remarkable happened concerning Hercules. Not far from the city, in a rocky way, the oxen made impressions with their feet, as if it had been in wax; and the same thing happening to Hercules, he thought his immortality was in part sealed to him." It can scarcely be doubted that these impressions were made in asphaltum, from which circumstance the myth may have originated, for the same thing is frequent on the asphaltum pavements of cities laid by unskillful workmen, and in California localities where soft asphaltum crops out on the surface of the earth.

Asphaltum was largely used in the building of Babylon, and the mention of this fact is of frequent occurrence in ancient writings.

Herodotus (Clio 179) thus describes the laying of brick in that ancient city: "Eight days' journey from Babylon stands another city called 'Is.' It is on a small river of the same name which discharges its stream into the Euphrates. Now this river brings down with its waters many lumps of bitumen from which the bitumen used in the wall of Babylon was brought. * * * As they dug the moat, they made bricks of the earth that was taken out; and when they had molded a sufficient number, they baked them in kilns, and then making use of hot asphalt for cement and laying wattled reeds between the 30 bottom courses of bricks, they first built the sides of the moat and afterward the wall itself in this manner."

Strabo (Book 16, chap. 1) in writing of the hanging gardens of Babylon, informs us that "the pillars, the walls and the terraces are constructed of baked brick and asphalt. * * * On account of the scarcity of timber (at Selencia), the beams and pillars of the houses were made of palm wood. They wove ropes of twisted reeds round the pillars, painted them over with colors and draw designs upon them. They cover the doors with a coat of asphalt. * * * The walls were of brick cemented with brimstone (asphaltum). * * * In the middle of the city she (Semiramis) built a temple to Jnpiter which the Babylonians call Belus, of which, since, writers differ among themselves, and the work is now wholly decayed through the length of time. There is nothing that can be certainly related concerning it, yet it is apparent that it was an exceeding great height, and that by the advantage of it the Chaldean astrologers exactly observed the rising of the stars. The whole was built of brick cemented with asphalt with great art and cost. * * * There are many remarkable and wonderful things to be seen in Babylon; but among these the great quantity of asphalt that flows out of the ground is not to be the least admired, which is so much that it not only supplied all their occasions in building such great and mighty works, but the common people gather it profusely, and when it is dry, burn it instead of fuel. And though it be drawn out by an innumeral company of people, yet it is as plentiful as ever it was before." (Book 2, chap. 27).

"Semiramis sunk in the low grounds of Babylon a place for a pond, four square; each square was 300 furlongs (nearly 40 miles) in length lined with brick cemented with brimstone, and the whole 35 feet deep. Into this having first turned the river, she made a passage in the nature of a vault from one palace to another, whose arches were made of firm and strong brick and plastered all over on both sides with bitumen, four cubits thick. * * * The

river was turned into its ancient channel again so that it flowed over the whole work. Semiramis could go from one palace to the other without passing over the river." (Book 2, chap. 1).

Diodorus Siculus, describing the building of Babylon by Semiramis, frequently mentions asphaltum being used very largely in the construction of walls and buildings.

Describing the hanging gardens, he thus mentions the use of asphaltum: "Over the several stories of the fabric were laid beams and summers of huge massy stones, each 16 feet long and 4 broad. The roof over these was covered with reeds daubed with an abundance of brimstone (asphaltum). Then upon them were laid double tiles pargeted together with a hard and durable mortar and over them all was a covering of sheet lead, that the wet that drenched through the earth might not rot the foundation."

"Alexander, marching toward Babylon through the country lying between the rivers Tigris and Euphrates, came to a city called Memmlum, where there is a fountain within a cave that belched out a quantity of pitch (asphaltum), so that it appears that the Babylonians had their cement from thence, which they employed about the making of their walls of an incredible breadth and compass."

Quintus Curtius Rufus (Life and Death of Alexander the Great, English translation, London, 1861, folio 100): "The beauty and pleasantness of that city (Babylon) gave just occasion to Alexander and such as were with him to admire it much. Semiramis was the builder thereof, or, as some affirm, Belus, whose palace is to be seen there. The walls are made with brick interlined with pitch. They be two and thirty foot in breadth, so that two carts may easily go upon them in front. * * * The river of Euphrates doth run through the midst of the city and is kept in on all sides with walls of wonderful workmanship. But the great channels, made of brick and fastened with pitch instead of mortar and wrought low within the ground to receive the violence of the stream, do exceed all the rest of the works there made, for, except the same were of quantity and largeness to receive the water when the stream floweth over the banks that be made to keep it in, the violence thereof would beat down the houses of the city."

Vitruvius (Architecture, Book 8, Chap. 3) refers to the "vast lake at Babylon called the asphaltic pool. * * *

In the island of Zacynthus (Zante) and about Dyrrachium and Apollonia are springs which throw up a great quantity of pitch with the water," * * * "contains floating bitumen with which, and with bricks of baked earth, Semiramis built the wall around Babylon. At Jopa, also in Syria, and in Numidian Arabia are lakes of immense size yielding large masses of bitumen, which is taken away by the inhabitants of the neighborhood; this is not, however, surprising, for at that spot there are many quarries of hard bitumen, hence when the water bursts out from this bituminous earth it carries it herewith, and, having come forth, the bitumen is separated from it and deposited." The Dead sea in Syria is a noted ancient locality of asphaltum. It is frequently mentioned by writers, both sacred and profane.

This remarkable sheet of water, which in many ways resembles lakes Mono and Owens in California, lies 1208 feet below the level of the ocean, and the climatic conditions are such that it is difficult for human life to exist there. For this reason, no thorough exploration has been made of it in modern times, and we must trust to ancient history and the reports of a few superficial modern surveys for all we can know of the geology of this region and, for that matter, the geography also. If it were possible to make as perfect an exploration as has been made of Death valley in California, there is reason to believe that deposits of asphaltum would be found equal perhaps in extent to any now known in the world. Information gained from sources mentioned would seem to warrant such an opinion.

(To be continued.)

A Doubtful Experiment.

The *Bulletin* says that Henry Spencer, a Colorado miner, is equipping a small naphtha launch for a novel prospecting venture on the Sacramento river above Redding. The launch is forty feet long and propelled with an eight-horse power engine. In the bow of the boat he has placed a peculiar pump, which was constructed from his own design.

The pump is calculated to suck up the mud from the bottom of the river and throw it on a sluice which runs the full length of the boat above the cabin, and extends far enough over the stern to throw all the refuse back into the river. It is claimed that the apparatus will work nearly a thousand cubic yards of mud a day.

Experiments of this character, says the Nevada City *Transcript*, have been tried at different periods in the past on several streams in this State and none have proved suc-

cessful. Large sums of money have been expended at different points on the Feather river, one company with a large boat being at work now a few miles below Oroville. This company has not yet found the gold, but they pumped, dredged and raised mud in quantities for some time and caught one large eel.

Gold, except of the very finest kind, will not stay in mud but sinks to the bottom and when found it will require unusual pressure to raise it by suction. Many times when gold is found in the bottom of a stream it requires to be dug out of the crevices with a sharp instrument to get it, and in some instances a knife and spoon are necessary.

The Allotropy of Gold.

The following is from the Transactions of the American Institute of Mining Engineers, and was read by Henry Louis, London, England, at the recent Virginia Beach meeting:

It can scarcely be considered a matter of doubt, in the present state of our knowledge, that the existence of, at any rate, two well-marked allotropic modifications of gold can be recognized, namely (a), the ordinary, yellow variety, and (b) the red, brown or purple, non-lustrous, amorphous variety.

There are, indeed, not wanting indications that still other allotropic forms may be capable of existing. It is, for instance, possible that the green colors of gold obtained under certain conditions, or that the black powder produced when the alloy of gold with potassium is decomposed by water, may represent further allotropic modifications, although this proposition is open to doubt. It can scarcely be pretended that the two first-named varieties have been absolutely isolated, yet it is, perhaps, quite permissible to speak of the ordinary and the amorphous modifications as having a proved existence.

Ordinary gold is sometimes found crystallized in nature, although never in a state of purity. When gold is melted and cooled slowly, its surface shows crystalline markings, and the fact that it is capable of crystallizing in the cubic system may be looked upon as established. When gold is produced by precipitation, the form which it assumes is dependent on the conditions of precipitation. G. Rose says that gold precipitated by ferrous sulphate from very dilute solutions is so finely divided that no regular form can be recognized, but in more concentrated solutions the precipitate consists of minute cubes. When oxalic acid is used as a precipitant, the gold is coarser and forms octahedral crystals. J. Thomsen has obtained similar results. Working with dilute and with highly dilute solutions, I have myself been quite unable to recognize any crystalline structure, even under the highest powers of the microscope; nor did there seem to be even any tendency of the particles to group themselves into arborescent forms, such as might indicate incipient crystallization. Precipitates from solutions containing between 0.0001 and 10 per cent of gold gave no indications of crystallization, even when magnified 800 diameters.

Thomsen has also pointed out that the physical characters of precipitated gold differ according as it has been precipitated from solutions of its chloride or its bromide. He also found that these different forms possessed different degrees of thermic energy, and hence deduced a strong argument in favor of their being allotropic varieties.

The specific gravities of various forms of gold differ considerably. G. Rose found that fused gold had a density of 19.3336 after it had been compressed in a coinage press, it being a little lower before this mechanical treatment. The density of precipitated gold thrown down by ferrous sulphate was found to vary from 19.5419 to 20.6882, the highest figures being obtained from extremely dilute solutions, the precipitate from which showed no trace of crystalline form; when precipitated by oxalic acid its specific gravity was 19.4791. When such amorphous gold was struck in the coinage press, its density became reduced to 18.0194. I have found that the density of gold left on dissolving out various metals alloyed with it, when the gold remains behind in a brown, amorphous, lusterless condition, varies between 20.3 and 19.5.

It is only fair to notice that Rose did not ascribe the differences in the densities of the different forms of gold to allotropism, but has suggested another explanation which is hardly, to my mind, a sufficient one. It is probably safe to assume that there are two modifications of gold—one a light one, of density 19.3 or thereabouts, and the other a heavy one, the density of which approaches 20.7—whilst various combinations of these extreme forms are capable of occurring.

In this connection the curious divergencies in the densities of specimens of native gold, from different localities but of about the same composition, may also be referred to; allotropism may, at any rate, be suggested as a possible explanation of them. There are thus sufficiently well-

marked differences in physical characteristics to support the hypothesis of allotropism.

As regards chemical properties, Thomsen has also pointed out that when amorphous, pulverulent gold is acted on by chlorine or bromine, auric compounds (Au_2Cl_4 or Au_2Br_4) are produced; whereas, these same substances produce auric compounds (AuCl_3 or AuBr_3) with ordinary gold.

I have found another point of difference, of far greater practical importance, in the behavior of these modifications toward mercury. Ordinary gold, of course, amalgamates readily, as is well known. I have found that gold precipitated from highly dilute solutions by ferrous sulphate is not attacked at all by mercury when freshly precipitated, and only slightly after drying on an air bath. Near the boiling point of mercury, partial amalgamation took place, but it was by no means complete. Mercury containing a large amount of sodium amalgam was equally without effect on the dry gold, although it readily and completely amalgamated it when moist. In these observations I seem to have been partially anticipated by Ludwig Knapp, who, however, appeared to attach little importance to his observations. In a brief note on the preparation of certain amalgams of gold, he says:

"Gold precipitated by green vitriol or mercurous nitrate is not suitable for amalgamation, as it is too finely divided and always floats on the surface of the mercury as a black powder, whether heated mercury be poured upon heated gold or vice versa. I examined this floating black powder and found it to contain gold and mercury. * * * Gold precipitated either by means of arsenious acid or by boiling a solution of the chloride in amyl alcohol, when it separates out in small, lustrous octahedra, is best suited for amalgamation."

It may also be added that the purple of Cassius, which probably contains an allotropic modification of gold, is not attacked by mercury. The black pulverulent form of gold, resulting from the decomposition of the potassium gold alloy amalgamates pretty readily, as does also the coherent pale brown powder produced by precipitating with sulphurous acid a strong solution of auric chloride.

All forms of gold are converted into the ordinary yellow, lustrous variety by the action of heat. A very high temperature is not required, but the exact point has not yet been determined; it is certainly well above 200°C ., but probably under 600°C . Powerful mechanical action, such as percussion, friction or compression, has the same effect.

I do not pretend that the above data form anything like a complete chain of evidence proving irrefragably the allotropism of gold, or that our knowledge of this subject is precise or definite; yet I venture to think that the facts do warrant us in looking upon the following deductions as probably correct:

1. Gold is capable of existing in allotropic modifications.

2. One of these modifications is capable of amalgamation only with great difficulty, if at all.

3. This modification is capable of being produced and of subsisting under conditions that may reasonably be supposed to exist in nature when gold is deposited in reefs.

Whatever may have been the nature of the solution by means of which gold has been introduced into the deposits in which we find it, whether as a soluble haloid salt, as is generally supposed, or as an alkaline aurate, as I venture to suggest, it may have been precipitated from such solution in various ways and under varying conditions. We have but few indications of the cause of this precipitation, but it is reasonable to conjecture that such reagents as ferrous sulphate or sulphurous acid, both resulting, perhaps, from the slow oxidation of iron pyrites, may have found their way, in solution, into the fissures within which the gold solution was circulating, and may thus have caused the deposition of gold within the reefs. Now, if the gold, thus deposited from highly dilute solutions, happened never to be exposed to a particularly high temperature, or to violent mechanical action, the conditions would be favorable to the production of that allotropic modification of gold which is indifferent to the action of mercury. In other words, under the above conditions, an auriferous deposit will have been produced in which a greater or smaller part, or perhaps even the whole, of the gold is what gold miners term "rusty." I have little doubt that the "rustiness" of gold is in different cases due to widely different causes—that, in fact, there is more than one kind of "rustiness;" but I venture to think, also, that there is sufficient evidence to warrant us in classing allotropism among

such causes of "rustiness." If this is correct, I need hardly point out either the great practical value or the application of this deduction. The gold which is thus allotropically indifferent to mercury is in a condition in which it is readily attacked by such reagents as chlorine and potassic cyanide. I have pointed out long ago that the gold of the Witwatersrand deposits of the Transvaal was probably deposited *in situ* under some conditions as I have sketched above, and it is now notorious that a large portion of the gold in them is not attacked by mercury, but readily by potassic cyanide solution. Again, in some cases it may be economically feasible to convert the non-amalgamable modification of gold into the common amalgamable variety by heating the ore to a moderate temperature, or the same end may be attained by mechanical means. In any case, the only really sound method of preventing losses of gold in the process of gold extraction is that of ascertaining, in the first place, the ultimate causes of such loss; and I venture to hope that it will be found that among such causes, the one here treated of—namely, allotropism of gold—will be found worthy of more consideration than it has hitherto received from scientific gold miners.

Indian Currency and the Far East.

The London Times says: "The China Association of Shanghai has addressed a long communication to the Government of India on the recent currency policy of the latter and its effect on the trade of the far East. Its propositions are summarized as follows: (1) As foreseen, the close of the mints in India was the primary direct cause of a heavy fall in the gold value of silver, and of creating an artificial difference in exchange between India and the far East to the extreme prejudice of the commerce between them. (2)

HOTEL RUBIO, MT. LOWE RAILWAY.

The difficulties surrounding British trade in the far East are increased by the uncertainties of further legislative action, especially in the matter of an import duty upon silver, which would have an immediate fresh disastrous influence upon the situation. (3) If British interests in the far East are recognized by the Indian Government and identified with their own it will be possible to unite on a silver basis, the adoption of which the Imperial Government will be unable to resist without exposing themselves to the accusation that for the benefit of certain capitalists, who alone at present derive benefit from the appreciation of gold and the disturbance of the world's system of exchanges, they have endangered the interests of the mercantile and industrial classes. (4) Persistence in such measures would have the utmost influence in inducing the Imperial Government to meet a conference of the nations concerned in the adjustment of the currency question, with a desire to secure an arrangement which shall restore the solvency of the Indian empire and place British trade on the sound foundation it occupied before the violation of the bimetallic ratio. (5) If, on the contrary, the Indian Government declines to regard the appeal of other British subjects in the far East, and persevere in expedients which cannot succeed, it is to be feared the Imperial Government will await the issue of events, and the prospect of international agreement will become remote. (6) To give effect to these representations there would seem to be no alternative to reopening the mints of India, and to have recourse to other methods of increasing the national revenue in order to compensate for losses caused by exchange. The letter concludes by an 'emphatic protest' against the imposition of an Indian duty of five per cent on all imports save gold and cotton goods, because of 'the damage and loss such action will inflict upon British interests in Great Britain, India and the far East.'

Mount Lowe Railway.

There are doubtless but few of our intelligent readers who have not heard somewhat of the Mount Lowe Railway. It is situated near to Los Angeles and Pasadena, and connects these two southern California cities with the majestic Sierra Madre range of mountains. This range has been called by the poetic people of the south, Apennines, the Pasadena Alps, for, as its name implies, it is a sheltering mother, protect-log its sun-kissed and flower-bedecked garden of the Lord from the winds which blow strongly in other regions. Picturesque and bold it stands, seamed with deep canyons, wooded gorges and precipitous cliffs. Its serrated summits look near enough to reach them by walking an hour, for the transparent atmosphere deceives. Its peaks are higher than the highest peaks of the White mountains, and one is instinctively seized with a desire to scale them and look down upon the fair panorama beneath.

This chain of mountains runs transversely across southern California, near the 34th parallel of latitude.

The Los Angeles Terminal Railway directly connects with the Mount Lowe Railway at Altadena Junction. Well-equipped passenger cars, fitted up with the most approved electric power, speed up Lake avenue, and in a few minutes land passengers at Hotel Rublo, from which point start the "White Chariots" of the Great Cable Incline, which latter has been designated "the most wonderful railway of the world."

At Altadena, also, are located the gas engines, working the electric dynamos which supply power for operating the trolley road to Rubio Amphitheater. These consist of two 60-horse power and one 100-horse power gas engines, with a capacity much larger than their specified amount.

The great cable incline called forth the praise of many engineers.

It extends from Rubio Pavilion, 2200 feet above the sea, to the summit of Echo mountain, 3500 feet in altitude. It is upward of 3000 feet in length, and makes a direct ascent of about 1300 feet.

The cars are permanently attached to an endless cable, and are so balanced that, in ascending and descending, they pass each other at an automatic turn-out, exactly midway on the incline.

The cable is of the finest steel and was thoroughly tested to a strain of one hundred tons; and, as under any circumstances the loaded cars will never exceed five tons, its absolute safety is at once apparent.

As visitors ride up this great incline, few realize the arduous labor it represents. Not only were the ordinary difficulties of railroad building to be overcome, but the grade was such that burros had to carry cement and water for building the walls and buttresses, which, in places, were necessary ere the track could be laid; and as there were many points where not even burros could climb in safety, men carried the required materials on their shoulders. It will be apparent how much labor and cost were expended in its construction; and yet, up to the time of laying the last rail, it was the money, energy and engineering skill of one man who accomplished it, when the great majority, with less foresight and courage, regarded the undertaking as well nigh impossible.

OXYGEN GAS has been used successfully as an antidote in an extreme case of morphine poisoning.

GREAT CABLE INCLINE OF MT. LOWE RAILWAY.

GLEN CANYON NEAR ECHO MOUNTAIN.

Pocket Mining.

What is more encouraging and causes a person's mind to be chuck full of life and enthusiasm than to go forth in the fields among the hills on a bright, sunny, spring morn, with a pick, pan and shovel, as an honest pocket miner, in search of the hidden treasure which has been forever buried from the eyes of man. Every dollar that is taken out adds that much more to the circulating medium to supply the wants of the human family. The mode of mining as it has been followed by the pocket miners in the foothills of El Dorado county, and in the vicinity of the railroad station at White Rock, requires experience in this special kind of mining—that is, to know just where to prospect, and when to follow up a trace and when not to. The experience of most all pocket miners in the localities above referred to is that most of the gold deposits lodged in the pocket ledges have almost invariably been taken from near the surface, and scarcely ever at a greater depth than 20 or 30 feet. In prospecting by a pocket miner he commences with a pan of dirt from the surface, and if a trace of fine gold is found, with a favorable formation of the surroundings, he again takes another, and another pan of dirt, and if there is found a considerable quantity of flour gold, it generally is considered a good prospect, and then a search is made for a quartz ledge, which is prospected on until a pocket is taken out or the prospect pinches out and the mine is abandoned, which, perhaps, may be for years; and then some one else will go into the same prospect hole and continue the work a little farther and succeed in striking the prospect.—Folsom Telegraph.

Glen Canyon near Echo Mountain.

That portion of the Sierra Madre mountains reached by the Mount Lowe Railway is seamed with deep and picturesque gorges and canyons. Rubio canyon, as far as Thalehaha Falls, has been made accessible by plank walks, bridges and staircases. Over thirty thousand feet of lumber were carried on the shoulders of the workmen to build these walks, etc., for, prior to their erection, this canyon was absolutely inaccessible to the ordinary traveler. Rubio canyon, above Thalehaha, is known as Echo canyon, as it is the gorge immediately to the rear of Echo mountain. Then where it turns directly into the heart of the Front Range it is known as Glen canyon, for there is one large, wide glen and several smaller ones within its folds.

The engraving gives some idea of the deep serenity of this canyon.

At the sight of the beauties of this hidden spot, the foot is stayed in reverent wonder as the eye instinctively measures the depth of the canyon by the branches of trees which rear high their lofty heads to seek the sunlight. Even above the tops of these trees perpendicular walls rise on either side, which, from top to bottom, are garnished with mosses, ferns and pendant shrubbery.

Huge boulders turn the course of the little stream hither and yonder, in places forming quiet, limpid pools, then hurrying along as if on some forgotten errand.

Mind and eye absorb the surrounding scene; the nostrils inhale the indescribable mingled fragrance, and the heart is insensibly lifted in adoration from this marvelous creation to its Creator.

Scientific Progress.

To Protect Boiler Interiors.

The frequency of troubles with steam boilers, especially those used on seagoing vessels, caused by incrustation and corrosion, has been a source of so much expense for making repairs, to say nothing of delays, that every process suggested to minimize the difficulties is given special attention. There have been compounds upon compounds used to prevent these decays, and some have been found to be good and some otherwise, and few, if any, have been tried that have not injured in some way the internal surfaces of the boiler. A novel method, called an enamelling process, has been the subject of careful investigation and practical experiment, and is reported to have given good results. The method consists in the coating of the interior surfaces with a deposit in the form of a smooth black film or enamel, similar to an electro deposit, thick enough to protect the metal underneath from corrosion, and so thin that the boiler loses none of its steam-generating power. The application is simple, the process material being injected into the boiler through a cock of lubricator pattern at such times as desired, and the surface below the water level thus becomes coated with the enamel. The makers claim for the process that the enamel is impenetrable by acids, it protects the boiler from the corrosive agents contained in almost all not all waters, it prevents incrustation and does not injure the boilers. It is also claimed to be inexpensive, is convenient of handling and effective in its purposes.

Harnessing Electricity to Light.

Professor Alexander Graham Bell is spending these months at his summer place in Nova Scotia, engaged in a series of investigations which may have important results. His outdoor work is devoted to experiments in "aerial navigation," in connection with Professor Langley of the Smithsonian Institute, while in his laboratory he is endeavoring to demonstrate the problem to which he has given a great deal of thought and in which he thoroughly believes. It is to harness electricity to light as it has been harnessed to sound, so that people may be able to see a great distance, just as the telegraph enables them to write and the telephone enables them to speak a great distance.

Professor Bell firmly believes that it will be possible some day to see from Washington to New York as easily as one can convey the sound of the voice that distance. He insists that the fact has already been demonstrated, and that it only remains to construct the necessary apparatus to bring the discovery into actual and practical use. This is exceedingly difficult, much more difficult than the construction of the telegraph instrument or telephone, for the reason that the vibrations of light are so much more rapid than vibrations of sound. But Professor Bell is confident that he will soon be able to discover a diaphragm sufficiently sensitive to receive the vibrations of light and produce the effect necessary to convey the impressions to the human vision.

At the recent meeting of the Numismatic and Antiquarian Society President Brinton exhibited, among other objects of interest from primitive Central America, a perfect facsimile of a book that had been made and printed in America before the discovery by Columbus. The volume in question is a work on astrology, and bears internal evidence of having been written about the year 1450. The word "printed" properly describes the method that had been employed in the production of the work, movable stamps of wood, terra cotta or stone having been used in imprinting the characters. The art of printing is generally associated in the

minds of persons of this generation with the existence of a very high state of culture among those who practice it; and when the Maya characters, in which the literary remains of this early Central American civilization are written, shall have been deciphered, the primitive inhabitants of this continent may be found to have reached a much higher degree of literary culture than had ever been supposed to exist.

A THEORY has been advanced by a Russian, who claims to have made a thorough investigation of the source of natural gas, that the gas was the product of the salt water, which is found in that locality from 1200 to 1500 feet below the surface of the earth, coming in contact with the molten carbides in the earth's interior. It is reported, says the *Chicago Journal of Commerce*, that he has partially proved the correctness of this theory by subjecting the salt water to the conditions and producing a gas which could not be distinguished from the natural article. He also subjected this gas to the conditions of a further development of this theory, and produced oil similar to the oil found in gas regions. Apparently, therefore, as long as the salt seas remain and the earth retains heat, the supply of natural gas is not likely to become exhausted.

THE new Alsite solder for aluminum is stronger than the metal which it unites. The surfaces to be joined are cleaned by dipping in a hot solution of soda or potash, then dipped into nitric acid, rinsed in hot water and dried. Sometimes they are cleaned by filing the edges. The parts are heated as hot as can safely be done without melting, and a small portion of the solder is spread over the edges by means of a brush, which should be kept heated during the process.

TREES are now felled to a considerable extent by electricity. A platinum wire, heated white-hot by the current, is used, stretched between two poles, as a saw. There is less work than with a saw, no sawdust is produced, and the charring of the surface of division tends to prevent decay. In some cases the time required to fell a tree by this method is only one-eighth of that necessary for sawing.

THE science of surgery continues to develop new wonders. Its latest success is supplying artificial bones to replace deficient portions of the skeleton. A Frenchman has for a year or more enjoyed more than ordinary health with such a substitute bone in his upper arm. The artificial bone is made of vulcanite and attached in place with platinum wire.

MARFAN AND MONROT, two eminent French physicians, have recently shown that broncho-pneumonia and various other pulmonary maladies occurring in children are due to infection resulting from chronic indigestion, often the result of incorrect feeding. This was found to be the case in 13 out of 18 cases.

SO SUCCESSFUL has the enlargement of the Lick Observatory photographs of the moon proved that it is believed practicable to make maps therefrom on a scale of ten feet for the orb's diameter. Director Holden says that three-foot or ten-foot atlases will soon be undertaken, showing the different regions of the moon.

THE extent to which smokeless powders are used for sporting purposes now is illustrated by the fact that nearly a hundred marksmen competed for \$600 and \$400 prizes recently at Dexter Park, L. I., and only one of them employed the old-style black powder, and that only in one barrel.

THE wind, according to Professor Langley, is not a continuous and sustained force, but a structure consisting of a series of puffs.

Professional.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Mechanical Progress.

The Age of Steel.

The man who inaugurated the reign of steel by so vastly increasing its uses, and invented a method which makes the product even lower in cost than the kind of metal it was destined so largely to replace, ranks among the world's greatest inventors, though, like other remarkable creative minds, he did not reach his goal unaided by the skill and genius of collaborators.

The pneumatic process of making steel, by which Sir Henry Bessemer added more to the wealth of the world than any man of his generation, furnishes a curious example of what Tyndall, says *Harper's Monthly*, called the scientific use of the imagination. Bessemer, like Siemens and Thomas, who share with him the honors of modern iron metallurgy, was not a practical worker in the metals, but, unlike them, he was absolutely ignorant of aught beyond superficial chemical knowledge.

When he grasped the conception of burning out the impurities of pig metal by the oxidizing power of air, and thus reducing the excessively carburized material to the malleable state, he knew nothing of the traditions and science of the problem he was daring enough to attack. Had he been an adept it is more than probable that he would have been so imprisoned by the past as never to have reached so daringly into the unknown. He began his experiments secretly in a small way, after having visited numerous iron works to make himself acquainted with the existing processes.

It was not till the end of eighteen months that the fundamental principles of his great future success became perfectly clear to him—that of rendering cast iron malleable by a powerful air blast blown throughout the charge and not merely on the top, as in the old finery and the puddling furnace.

The heat developed was so great as to keep even wrought iron fused, and the happy inventor found by and by that he had succeeded in making steel in small quantities. It cannot be related here how he fought through the early difficulties of his work, and how the ironmasters of the age were alike astonished and delighted at his primary results. The shock to the inventor was scarcely less great when he discovered that in making steel in large quantities his process did not answer all his anticipations. His earlier successes had been with a pig iron smelted from high-grade ore, comparatively free from sulphur or phosphorus.

The attempt to work the process commercially involved the use of the common pig, which made up the bulk of the smelting material. The intense heat of the furnace burned out the carbon and the silicon, but left the phosphorus and sulphur untouched. This might have been remedied by using pure pigs containing but traces of these elements; but a graver defect attended the process. In many of the operations the ingot had no consistency; it crumbled under the hammer or in the rolls. In the language of the shop, it was rotten. The process, which, within a month of its first public announcement at the Cheltenham meeting of the British Association in 1856, had brought to its discoverer the sum of £27,000 in advance license fees, was now condemned by scientists and practical men as a visionary scheme.—*New York Commercial Advertiser*.

Paper Pulp from Logs.

A new machine for grinding a log into paper pulp and producing a fiber believed to be much better than that obtained by the Voetter method is reported from New England, but without names of inventors or place of trial. The case of the machine is of metal, over one inch thick, and very heavily made. Throughout its surface it is pierced with holes and the inner surface is

corrugated. Within is a heavy cylinder, the outer surface of which is corrugated, the corrugations running in a direction opposite to those of the casing. When the cylinder is set in motion and a log of wood is placed between cylinder and casing, the corrugations strip the wood into a soft, fluffy, fibrous material, almost like cotton; so nearly like it, in fact, as to be mistaken for cotton by the uninitiated. In the last stage of the operation this fibrous material is forced through the holes which pierce the casing of the machine.

Heating Iron in Water.

Raising iron and steel to a welding heat by plunging them into a bucket of water is one of the more recent electrical accomplishments which has excited no end of interest and admiration. The phenomenon was illustrated experimentally to thousands of spectators at the Columbian Exposition last year, but instead of being simply an interesting scientific demonstration, as it was there regarded, it has latterly been applied in a practical way as an everyday substitute for the time-honored forge fire. At the Edison Illuminating Company's Pearl-street station, at Brooklyn, N. Y., the "water-pull forge," as it has been aptly named, can be seen in daily operation, and the practical value of its astonishing performances has there been demonstrated beyond all doubt. Across the top of an ordinary wooden water bucket rests a bar of iron, to which the negative pole of a dynamo is attached by a wire. The other pole of the machine is connected with a plate of copper in the bottom of the bucket. To bring the end of any desired bar of iron or steel to a welding heat, all that is necessary is to rest it against the bar across the top of the bucket and to dip the point into the water within. This closes the electric circuit, and in a few moments the end of the bar becomes hot enough to be readily worked under a blacksmith's hammer. What actually happens when the circuit is closed is this: The water in the bucket, under the action of the passing current, immediately begins to decompose into its component gases, oxygen and hydrogen, and the latter adheres in a film to the submerged part of the metal bar, protecting it from contact with the surrounding water. If now the electric current were not very strong it would cease to flow, because of the break in the circuit made by the hydrogen accumulation. With a sufficient strength of current, however, the resistance of the hydrogen envelope is overcome, and in doing this heat is developed—sufficient in this case to quickly bring the end of the bar to a white heat. That the water does not quench the bar is readily explained by the fact that the hydrogen film prevents the two from coming into actual contact. How great the possibilities of this water-pull forge are can easily be imagined. The ordinary forge and blower, and the necessarily attendant coal and smoke and dust, all are entirely dispensed with, and the whole outfit may be a likely feature of the ideal blacksmith shop of the near future.—*Cassier's Magazine* for May.

Engineering Skill.

An ingenious use made some time ago of a rapid river current in India aptly illustrates the fertility of resource of the average engineering contractor. At a certain point along the river a temporary bridge was urgently necessary for the transportation of materials to be used in the building of an important neighboring structure, but the only available material was a quantity of three-inch planking, about ten feet long and a little over three feet wide, and some ordinary round timber cut from a neighboring forest. Pontons were made of two single planks, placed about 15 feet apart, each plank being held on edge at an angle of about 50° from the vertical, both inclining up stream, and kept at their proper distance

by framing made from the round timber already mentioned. Both pontoons were moored to a chain. The peculiarity of the bridge, of course, was that the water pressure upon the inclined surfaces of the planks, due to the swift current, permitted them to carry a considerable load, and the structure served its purpose admirably, accommodating a pretty lively traffic for an unexpectedly long period.

Metallurgy and Ores.

SELBY SMELTING AND LEAD CO.

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

—AND— ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF—

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

—ALSO MANUFACTURERS OF—

Standard Shot-Gun Cartridges,

Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals. Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co., and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice

611 & 613 Front St., San Francisco, Cal.

Founded by Mathew Carey, 1785.

HENRY CAREY BAIRD & CO., Industrial Publishers, Booksellers and Importers,

810 Walnut St., Philadelphia, Pa., U.S.A.

Our new and Revised Catalogue of Practical and Scientific Books, 88 pages, 8vo., and our other Catalogues and Circulars, the whole covering every branch of Science applied to the arts, sent free and free of postage to any one in any part of the world who will furnish his address.

THE GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA. LIMITED.

TRADE MARK.

(McARTHUR-FORREST PROCESS)

MacARTHUR-FORREST PROCESS.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty. Advisory Board in the United States: Thomas W. Goad, Mgr.; Hugh Butler, Atty.; John F. Bell; P. George Gow.

OFFICE:

McPHEE Building, DENVER, COLORADO. Agency and Experimental Plant, Mechanical Arts Building, Midwinter Fair, San Francisco, Cal.

Electric Progress.

Possibilities of the Telephone.

The possibilities of the principles of the telephone are so great that they form an interesting field for the investigations and experiments of electricians the world over. The possibility of using the water as a method of telephonic communication are now being developed, and it is almost a certainty that before long moving ships at sea will be able to communicate with one another, though they are outside the range of vision, and that a warning of the approach of icebergs, derelicts or other ships will be given by electrical apparatus attached to vessels. Professor Cottadon has recently made interesting experiments in this line, and they have been repeated by Captain Neale, of the British navy, on the Thames. In sufficient depth under water a membrane was caused to emit vibrations of what electricians call a "definite color." These were transmitted through the water to a considerable distance and repeated on the membrane of a similarly constructed apparatus, whose membrane was "equivalent" with the membrane of the first apparatus. A telephone is attached to the apparatus, and thus the signals are transmitted to the place where they are wanted on board the vessel. In this manner signals have been transmitted for fifty miles. In 1892 Dr. Ernst Huber, of New York City, patented an apparatus of the kind referred to, and a company was formed to construct it. The Government took considerable interest in it, and offered Dr. Huber the privilege of using a man-of-war on his experiments. The invention attracted considerable attention at the time, but for some reason the proposed experiments were not made. Dr. Huber turned his attention to other things, and the invention was forgotten. Before getting his patent Dr. Huber made some successful experiments with his apparatus. In the Huber sea telephone the sound waves passing through the water cause metal strips to vibrate, and the vibrations are transmitted by wires to microphones, which greatly intensify them. A device called an indicator shows the intensity of the sound vibrations, and this gives an idea of the distance of the object causing them. By turning the apparatus, which is intended to be attached to the bottom of a vessel, the direction from which the sounds come can be determined. By an ingenious device all sounds made by the ship itself are eliminated, and only those made by extraneous bodies are felt and recorded. By ringing an electric bell attached to the apparatus, sound waves are spread in all directions, and are reflected back upon meeting an obstruction. When they are reflected back they affect the membrane of the apparatus and give notice of the approaching danger. Icebergs and submerged wrecks can be detected in this manner. The inventor declared that he was able with his apparatus to discover the presence of any obstruction within ten miles. The possibilities of such an invention, should it work successfully in practice, are immense.

Uses for Vagrant Electricity.

A great deal has been said in the last two or three years about the mischief wrought by electricity generated for lighting or trolley systems and returning to the central station through the earth. Even where the rails are used for return purposes, and are carefully joined by copper bonds, some of the current, it is said, still leaks away, and corrodes gas and water pipes, eats away the sheathing of telephone cables, and, by leaking small gaps, gives a spark that may be the cause of a disastrous fire. But certain incidental benefits resulting from such meanderings of electric energy are also reported occasionally. The difference in the potentials of two vagrant currents coming into houses in Cambridge, Mass., on water

and gas pipes is such that by connecting the two pipe systems there is a sufficient flow from one to the other to run small motors and incandescent lamps; and electric door-bells are also operated in the same manner. Referring to an old scheme for connecting telephones with gas and water pipes, and using the latter merely as conductors for a current otherwise provided, a writer in the *Electrical Review* recently expressed the belief that "In any of our large cities where the rails serve as the return conductor for railway currents sufficient current traverses the water and gas mains to conduct the above-described experiment, using the leakage current as the electric source for the two transmitting instruments."

Electrical Dangers.

The report of Electrical Expert Low to the Pacific Insurance Union, based upon actual experiment and observation, brings to light a new source of danger from electric roads in cities. Not only does electrolysis destroy water and gas mains, as has been stated before, but these mains, being good conductors, become charged with electricity, and wherever there is a break in the connection are ready to discharge the subtle fluid, as is the rule with all conductors.

By tests made along the lines of one of the electric railroads now in operation it was found that the mains of the Spring Valley Water Company and of the San Francisco Gaslight Company were highly charged with electricity. At one place a connection was made between the water main and the track through the volt meter, and a pressure of sixteen volts was recorded. The ampere meter was then connected, and it showed the startling figures of 116 amperes. When it is recalled that one-half an ampere is sufficient for a sixteen-candle power electric light the result of these tests will be appreciated.

Suppose that this powerful current, intercepted in some way, finds a leak in a gas main or pipe, or that it finds a conductor in a house connection from a water main or gas main, who could answer for the consequences? There might be a terrible explosion or a great fire, and nobody would be able to foresee it or guard against it. The vagaries of the electric current are not thoroughly understood, even by scientists, but enough is known to enable any one to comprehend the danger which lies in vagrant electricity.

Something will have to be done to correct these manifest evils attending the trolley system, or the system will have to be abandoned in cities. In the country, where iron mains and pipes are unknown or are very rare, the leakage of the electric fluid may be innocuous, but in cities it is such an obvious element of danger to the community that some method must be devised to prevent it.—Chronicle.

Mechanical Force Derived Directly from Coal.

With certain transformations of energy of chemical action into electricity, of electricity into light or heat, and of heat into power, every school-boy is as familiar as he is with the general principle of the mutability of force. But some interesting experiments lately conducted by H. Carey Lea reach out into a new department of this field of thought. He has been trying to see whether he could produce chemical change from mechanical energy. Light, as one discovers in photographic experiments, has the effect of darkening and reducing, or disintegrating, certain salts of silver, bromides and iodides. Mr. Lea finds that he can produce similar results merely by compression. In some of his attempts he exerted a pressure of a million pounds to the square inch.

From a commercial point of view this is a valuable expedient; but a principle has thus been established. Now, what the physicists would like to know is whether that opera-

tion can be reversed and chemical change can be made to yield mechanical force directly. In a primary, or a secondary battery, chemical action produces electricity, and this can then be converted into mechanical force. So, too, by burning we get heat, and then can turn heat into power. But what certain investigators are trying to ascertain is whether the intermediate stage cannot be dispensed with, and, if so, how. The particular object in view, or at least one important aim in this inquiry, is the discovery of a way to obtain from coal something like the full amount of energy that is stored up in that familiar compound. It has been asserted that by our best methods of combustion, in connection with a steam boiler and engine, only about one-tenth of the work is extracted which the sun placed on deposit therein away back in the vegetative processes of the carboniferous era. A tremendous revolution in the methods and cost of all manufacturing operations and in propelling cars and ships would be wrought if ever a secret of this sort were wrung from Nature. And her mysteries, it is safe to say, are not yet all unravelled.

Branding by Electricity.

A novel system of branding horses, cattle and sheep is reported from Australia. The brand is kept the required heat by electricity from storage batteries. From these a flexible rubber tube carries the electric energy to the brand, which is heated from within. It is claimed that this brand is perfectly safe, that it marks without a blotch, and is kept at a uniform temperature.

THE ship channel from the Gulf of Mexico to the city of Mobile is soon to be lighted by electricity. The plant will be the largest so far used for a similar purpose. The channel is thirty miles long, and the alternating current system has been adopted.

THE Niagara Falls electrical power plant will not be ready for service, it is now announced, until October. The tunnel opening was first expected in February last, and then a postponement until June was necessary.

THE current required by the electric rail-welding process of one of the leading makers of machinery for this purpose has a volume of 50,000 amperes, but a potential of only four volts.

OVER 200 electric street-railway lines in the United States are now equipped in whole or in part by electric heaters. Their superiority to the coal stove in every respect is obvious.

AN unconfirmed report is that a North Dakota engineer has invented an electrical boiler alarm, which gives timely warning of conditions conducive to explosions.

THE *Electrical Review* learns that a Frenchman has invented an electric mosquito bar which electrocutes insects which come in contact with it.

THE city statistician of Chicago reports that there are 150 establishments for "electric light, works and materials" in that city.

THE cost of transmitting electricity from Niagara Falls to Albany is estimated at \$27.53 per horse power.

A SWEDISH COPPER MINE has been worked without interruption for 800 years. In 1650 it produced enough copper to have met the requirements of the whole civilized world, and it is estimated to have had a total yield in eight centuries of 1,200,000 tons, worth—at the average value of \$140 per ton—more than \$160,000,000. A record of its production has been kept for 261 years. The output was 1336 metric tons in 1633, reaching a maximum of 3445 in 1650, and slowly decreasing since 1690, being 271 tons in 1891.

Practical Information.

Rosin in Beer Kegs.

If you should happen to get a smack of rosin in your glass of beer, as it is quite likely you may at this time of the year, don't imagine that the brewers are substituting pine shavings for malt and hops to make the beer from.

Some brewers, says the New York *Sun*, are guilty enough, perhaps, as it is, with their substitutions of corn, rice and glucose for malt, but they do that simply because you insist upon having light colored beer. The reason why you may detect a rosin flavor now is that this is the season when the brewers pitch their kegs.

It may interest you to know that the beer you drink never comes into contact with wood, either in the kegs in which it is delivered or in the great vats in which it is fermented. If it did, the wood would sour and spoil the beer. The vats are protected on the inside with repeated coatings of shellac varnish, renewed whenever it is necessary. This used to be an exceedingly dangerous operation before the general introduction of incandescent electric lights; for an open light was liable to set fire to the fumes of the alcohol used in the varnish and produce disastrous explosions in which men were maimed or killed.

The pitching of the kegs is an interesting process. When a keg is empty and the bung and vent plugs are out, stick a lighted candle into the bung and look into the vent-hole. You will think you are looking into a glass barrel. Every part of the inside glistens. The keg has a complete coat of rosin. After a year's use this gets many minute cracks in it and needs to be renewed, and the springtime is the brewer's favorite time for doing this, before the great summer trade begins. The drivers do not enjoy pitching time, for they have to do the work, helping the brewery coopers. As they bring back their loads of empty kegs—sixths, quarters and half barrels—these are ranked up next to the wash-house, where a big kettle of boiling rosin is ready for use.

Before the new rosin is put in the old coating is to be melted out. A curious machine with two arms is the first of the devices that comes into use.

The kegs are hung on this, with an arm of fire thrust into the venthole. Presently a stream of boiling rosin comes from the open tap. A keg is taken off, tipped over a barrel where the waste rosin is poured out, and passed to a cooper. He sounds the head, discards the keg if it is defective, but if not drives a plug of wood home in the vent and passes the keg on. One man now pokes a long-handled funnel into the tap-hole and another pours a ladleful of boiling rosin into the keg from the kettle.

A cooper seizes the keg, drives another wooden plug home into the top hole, and gives the keg some curious twirls which spreads the rosin over every part of its interior. Then he knocks both plugs out and tosses the keg upon a set of rollers going slowly around by steam power. Here the surplus rosin runs out and the keg rolls until the rosin which remains cools and sets.

The kegs are rolled into the wash-house, ranged up on end, the rosin burned out of the vent and tap-holes, a new plug put in the vent, and the kegs filled with water. The water is meant to soak out the rosin taste. As fast as these operations are finished a man with a paint pot and brush follows along the line and puts a dab of paint on the front of each keg. If the kegs were marked with white at the last pitching time he uses red, or white if it was red before.

In the Cascade mountains, about 75 miles northeast of Jacksonville, Oregon, the seeker for the curious will find the great sunken lake, the deepest lake in the world. This lake rivals the famous valley of Sinbad

the Sailor. It is said to average 2000 feet down to the water on all its sides. The depth of the water is unknown, and its surface is as smooth and unruffled as a mammoth sheet of glass, it being so far below the mountain rim as to be unaffected by the strongest winds. It is about 15 miles in length, and about $4\frac{1}{2}$ miles wide. For unknown ages it has lain still, silent and mysterious in the bosom of the great mountain range, like a gigantic trench scooped out by the hands of a gigantic geule.

Acreage Under Irrigation.

Following is an estimate of the acreage of land now under irrigation in the United States, together with the number of acres under cultivation. It is believed that California has not only a greater area of land under irrigation systems, but a larger per cent of the irrigable land is cultivated than in any other State or Territory except Arizona:

	Under Irrigation	Under Cultivation.
Arizona.....	650,000	400,000
California.....	5,500,000	3,800,000
Colorado.....	4,000,000	2,000,000
Idaho.....	1,500,000	375,000
Kansas.....	300,000	125,000
Montana.....	1,500,000	400,000
Nebraska.....	350,000	100,000
Nevada.....	200,000	100,000
New Mexico.....	900,000	400,000
North Dakota.....	15,000	5,000
Oklahoma.....	10,000
Oregon.....	300,000	120,000
South Dakota.....	125,000	75,000
Texas.....	400,000	185,000
Utah.....	750,000	430,000
Washington.....	1,000,000	200,000
Wyoming.....	1,500,000	200,000
Totals.....	18,000,000	8,915,000

With the completion of the irrigation systems now under construction it is safe to say that 50 per cent may be added to these figures.

How to Make Whisky.

It is a very simple matter to make an illicit still. A man who knows how can make one in a very few minutes, and it will cost practically nothing. The moonshiner frequently takes an old sprinkling can and solders the top on tight. Then he arranges a bucket of water and cuts a hole near the bottom of the bucket to allow the rubber hose, which he will attach to the spout of the sprinkling can, to pass out after he has coiled it in the bucket and thus made a worm. Then he pounds up some corn and puts enough water with it to make a mush, fills his sprinkling can, builds a fire under it, and there he has a still. The steam which arises from the mush is condensed as it passes through the hose, and when the condensed liquid trickles out of the other end it is whisky.

A Good Point About Cable Cars.

Some people have an idea that when anything goes wrong with the cable the car may suddenly begin moving at some terrific rate of speed, carrying everything before it until it dashes itself and its unfortunate passengers to pieces. Any one who takes the trouble to think about the matter will realize that under no circumstances can the car go faster than the cable itself, or eight miles an hour.—Scribner's.

ANOTHER RAILROAD that transfers trains with locomotives by means of huge ferry-boats is the Baltimore & Ohio. An entire express train—and a lot of coal cars also, perhaps—is regularly ferried from Canton to Baltimore on the Robert Garrett, across the "northwest" branch of the Patapsco.

THE oldest piece of wrought iron in existence is believed to be a sickle found near Thebes. It is about 4000 years old.

If one could sell the sea at one cent per 10,000 gallons it would bring \$25,000,000,000.

THE Cramps propose to hold for the construction of some of the new British war vessels.

524 SACRAMENTO STREET, - - SAN FRANCISCO, CAL.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ores; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Sinterification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ores Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables. The volume embraces 130 12mo. pages, with illustrations, well bound in cloth, 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Sulfate. One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter. Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

{ FRANK BARRERE, }
{ Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 180 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW ORE CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best. Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish. Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully, E. L. BALLOU, Prop. Balloon Reduction Works.

THE MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Kern.

THE DESERT MINES.—The rush to the Red Rock, Goler, Summit and Black Mountain mining districts still continues, and each day outfits pass through Mojave in their search of gold. In answer to inquiries the majority of prospectors state that they have nothing else to do and are taking the gambling chance of discovering gold or hope for something to turn up. It is needless to state that the majority of them return disappointed, and, what is worse, broke. All classes and followers of every trade and profession have become prospectors and are on the desert hoping against hope to obtain a portion of the desert gold.

Exaggerated stories concerning the amount of gold taken out can be heard on every hand, and with each repetition the story grows as everything else in this glorious climate. There is no doubt of there being gold in all these districts, but the amount has been very much overestimated. The greater number of the people going into these camps are not practical prospectors; they have never been on a desert and go wholly unprepared for the hardships which they have to endure.

At the stations of the borax company water can be secured when there is a surplus, but at other times it must be sought elsewhere. There is water six miles from Mojave, at a borax station; again at Nugeles, 16 miles from Mojave; at Red Rock, Kane Springs, 27 miles from Mojave; at Mesquite Springs, six miles farther. From the latter place water is hauled a distance of six miles to Goler, and to Summit, 13 miles. At these camps water is sold at \$1 per barrel of 50 gallons.

As in all mining camps, nearly as many leave every day as arrive, and the population shows but little increase.

At Red Rock but three mines are in operation—the Sullivan, Bonanza and one other. These are paying wages, or about \$4 or \$5 per day to the man. The reports of the fabulous wealth of the quartz vein known as the Mexican mine, are laughed at here as they are supposed to emanate from interested parties. It is a well-known fact to oldtimers that the same ore was discovered and worked in 1867 at a stamp mill erected about three miles above Red Rock, at a place which was known as Sageland. Negotiations are pending, however, for the bonding of the Mexican mine for \$10,000. There is but little use of a prospector going to Red Rock unless he wishes to buy, as all the ground is taken up for miles around.

At Goler there are, perhaps, a dozen men at work dry-washing, although a number of prospectors are on the ground.

At Summit not more than 15 men are mining, some of whom are not making board, while others are averaging \$10 per day to the man. Claims can be bought from \$2.50 up, and many are anxious to sell for anything they can get. The camp is not a very prosperous one, yet it is as lively as any of its neighbors.

Some discoveries have been made recently in the Black Hills, but their extent is not yet known. The difficulty with the entire district from Red Rock to Summit is that it is located and held only for speculative purposes. Color can be found in nearly every gulch, but gold in paying quantities has not been discovered in many places. None of these places can become mining camps of any magnitude until the horde of lazy, porcine speculators and land-grabbers are rooted out.

There is no grass on the desert, and horse feed has to be hauled from Mojave; water is a luxury and gold scarce. Taken altogether, the desert gold fields contiguous to Mojave are not the place for a poor man to venture into at present. Between the gambling sharks of Mojave, the scarcity of water and the high price of provisions, many leave here "sadder but wiser" men.

Canfield and associates, who bought the Bonanza claim at Red Rock and have since been purchasing adjoining properties, have now at Mojave a lot of pumping machinery. The plan is to pump water from Kane Springs right over the mountain—a raise of at least 1200 feet—and then use it on the western or Red Rock slope for eluvial and, possibly, hydraulic purposes. It is a big scheme and will cost pots of gold to carry out.

At the new mining camp in the desert, called Black Hills, the Lee Brothers have opened a bed of gravel, some 15 feet in thickness, which prospects finely in gold throughout. This district is about 12 miles northwest from Red Rock and entirely away from what has been considered the course of the Red dry river. It is another one of the peculiar features of that desert country, in the line of things that no one can explain. The lack of the camp is water, for so far there is nothing like a spring in the entire district.

Another discovery of quartz very rich in gold has just been made near Dove Springs. This region between the Mojave desert proper and Kelso valley has for years been known to have rich floats, and now both the mines recently discovered are producing very rich ore.

A man well posted in mining affairs, who has given the desert gold fields careful examination, states that it will be a poor man's country for years and years. As he expressed it, "If all the Industrials could be turned loose over there and were a mind to work they could make good wages for years and years." But he does not deem it a good place for investment and operation on a large scale by companies. And in this view he is undoubtedly correct.

It is stated that Guey Miller of Havilah is now mining antimony and selling it on the dump to San Francisco for \$20 a ton.

Add this to the hauling and crushing costs, and it will be seen that this is about equivalent to quartz that mills \$30 a ton in gold.

Lassen.

HAYDEN HILL.—Big Valley Gazette: Hayden Hill is reviving. We made a flying trip to that camp last Saturday, and found things looking more prosperous than they have for years. A new double shaft has been sunk on the Golden Eagle to a depth of 300 feet, and a force of eight men are now at work in the mine. Mr. W. B. Scott and Dr. A. G. Schloesser of Chicago, two of the owners of the mine, arrived at the Hill last week, and it is confidently expected that a still larger force will be put on soon. The mine is in charge of W. C. Howard as superintendent.

Nevada.

WILL BROIN BREASTING.—*Transcript*: Tomorrow the work of breasting out the gravel will begin at the Odin drift mine. Some very rich gravel has been uncovered there lately and there is enough in sight to keep a good force of men at work right along. More miners will be put on as room is made, but the increase will be gradual and places have been already promised to as many men as will be wanted.

FINE ROCK.—*Timings*: Supt. Waggoner brought in some very fine rock from the Granite Hill mine to-day, which came from a new ledge just uncovered. It is well filled with sulphurets and galena and shows considerable free gold. The Granite Hill is rapidly coming to the front.

DAISY HILL.—*Telegraph*: M. C. Taylor has received word from San Francisco that full arrangements had been made to start work on the Daisy Hill mine immediately. Charles Taylor, who is superintendent for the company, is expected to arrive here this evening or in the morning, and building will be started right away.

CEMENT MILL STARTED UP.—*Transcript*, May 28: Messrs. Ashman, Peterson, Simmons and Whalen started up their cement mill to-day. They have 80 tons of the cement in the mill and about 300 tons near the track. The cement deposit that they calculate to work is about 15 feet deep and covers two acres of ground, which they have leased for two years from Mrs. Storey. Water power to run the five-stamp mill has been brought from one of the town reservoirs, for which purpose 2000 feet of pipe was required. The mill will crush 20 tons every 24 hours and will be kept running day and night. The works are located in the old diggings off from Orchard street, and the material that is to be milled was left when the ground was worked by the hydraulic process a good many years ago.

Plumas.

THE PILOT PEAK MINE.—*National Bulletin*: Plumas Turner came down from Onion valley last Tuesday. From him we learn that a very important and rich development has been made in the Pilot Peak mine, a property which has been attracting considerable attention during the past year and which has been promising well. Last week Mr. Turner and others, having resumed development work, cut into a large vein of ore heavily charged with arsenical sulphurets carrying gold in such quantities as to make of the lode a highly valuable mining proposition. The tunnel is in 128 feet, and the face of it is 65 feet below the surface.

When the owners began prospecting the mine the ledge seemed to consist of a series of small veins carrying rich sulphurets. The present development indicates that all these veins converge into a big chimney of rich ore, and of a character new to miners in that part of the State. From the point where this strike has been made, Mr. Turner estimates the distance to the footwall to be 50 feet. The ore is about one-fourth sulphurets. The owners consider that they have one of the biggest mines in this part of the State. This property is situated on the northern slope of Pilot Peak, a mountain 7500 feet high, at the headwaters of Poorman's, Hopkins', Onion Valley and Dixon creeks. The first two particularly were very rich in placer gold, and in early days yielded up to the miners their thousands. The source of this gold was thought to be parts of rich ledges running into Pilot Peak in the vicinity of the mine under discussion. Mr. Turner is confident that his company has discovered the source of much of the gold found by the pioneers in such generous quantities in the streams below.

BIO YIELD OF GOLD.—*National Bulletin*: Word comes from Prattville that in five days Fred Scott had taken from the King drift mine on the North Fork the sum of \$700 in channel gold. We are glad to hear such good news. This property is at the lower end of Big Flat, through which for a distance of nearly four miles an ancient auriferous channel runs.

The Glacier mine is at the upper end of the flat, and the Angie Cameron mine is near the center. There is scarcely a doubt that here is one of the biggest mining propositions of the county.

San Bernardino.

VANDERBILT DISTRICT.—*Pioche Record*: James Clark of Desert Springs came in Saturday from Vanderbilt, where he has been residing for the past three months. He says that mining and milling are progressing favorably in that section, and there are not many idle men in camp. The great difficulty is the scarcity of water, which is a detriment to the steady run of the mills. Green Campbell is sinking on the Boomerang mine and as soon as water level is reached calculates to obtain sufficient water for all milling purposes. There is considerable prospecting going on in the neighboring hills for water, but so far the results are not favorable for any great supply. There are three men at work grading on this end of the railroad, but this is only a temporary force and will be increased.

Many men are chloriding on small streaks of

gold-bearing quartz, which will be run principally at the Bronze mill.

While there Mr. Clark met some Piochers, among them Dick Rich, who is carpentering at the Crescent mill; Hank Goodrich, who is erecting an assay office in connection with the Crescent mill, and Joe Goodrich is helping to put up some machinery at the same place. Places of amusement are springing up and the camp generally presents an air of activity.

NEVADA.

Washoe District.

CON. CAL. AND VIRGINIA.—1650 level.—The south lateral drift No. 3 in the ore body recently found started from the west crosscut 28 feet below the sill floor of this level and 14 feet under south drift 2 has been extended during the week 5 feet in good ore, total length of the drift in ore 26 feet; the face of the drift is all in ore which will average \$30 per ton. Most of the time was spent in completing the timbering of the drift, and work in the face was temporarily suspended, but the work of extending the drift will be resumed in a short time. South drift 4 on the 1700 level is being reopened for the purpose of being extended to traverse the ground at a depth of 22 feet below the south drift 3. The ore extracted during the week amounted to 131 carloads, about 129 tons, the average assay value of which, per car samples, was \$30.58 per ton. This ore came from south drift 3 and from south drift 1 on the sill floor of the 1600 level. 1000 level.—The Rile drift.—The upraise on the east side of the main drift at a point 535 feet south from the shaft station has been carried up 15 feet, total height, 65 feet, in porphyry, clay and quartz carrying some value. From the top of this upraise an east crosscut has been advanced 20 feet, face in hard porphyry. From the main drift at a point 370 feet south from the shaft station a west crosscut has been advanced 55 feet, face in porphyry and quartz.

In the Ophir mine no changes are reported in the 1465 level workings. In the old Central tunnel the north drift from the old Mexican shaft on the tunnel level has been extended 10 feet; total length, 53 feet. From this north drift at a point 26 feet north from the shaft a west crosscut has been advanced 21 feet; in porphyry and clay. The northwesterly drift started from the shaft on the west side, at a point 56 feet above the tunnel, has been extended 41 feet; total length, 83 feet, in porphyry and clay. The usual prospecting work was done on and above the 1465 level of the Mexican mine, with no changes in formation reported. On the 900 level of the Union shaft the Union Con. and Sierra Nevada joint west crosscut started near the north line of the Union Con. mine from the joint north drift at a point 1520 feet west of the shaft has been extended during the week 24 feet; total length, 112 feet; face in hard porphyry. From the joint west drift at a point 1520 feet west of the shaft a joint lateral drift has been advanced 10 feet; face in porphyry and clay. In the Andes mine the upraise from the west crosscut that connects the north lateral drift with the main north drift has been carried up 12 feet; total length, 23 feet; formation, quartz and porphyry. In the Sierra Nevada mine the west crosscut No. 1, from south lateral drift 660 feet south of intermediate tunnel, has been advanced 30 feet; total length, 105 feet; face in clay and porphyry.

In the Best & Belcher mine on the 200 level they started on north boundary a northwest drift 1115 feet from main northwest drift and advanced same 16 feet, passing through porphyry and quartz giving low assays. 800 level.—Northwest drift started in crosscut 2, 415 feet from main north drift, has been extended 14 feet, passing through quartz and porphyry; total length 26 feet. In the Gould & Curry mine on the 200 level west crosscut 5 started in northwest drift 432 feet from the main west drift has been extended 19 feet, total length 1100 feet; passing through hard porphyry.

In the Potosi mine, on the 450 level, the south drift is in 494 feet. The face is in porphyry and low-grade quartz. The west crosscut from this drift, 200 feet from the north line, is in 131 feet. The face is in low-grade quartz. In the Chollar mine the north drift on the 100-foot level is in soft porphyry. The west crosscut from the lateral drift 300 feet south of the north line on this level is out 309 feet. The face is in porphyry and quartz, the latter averaging from \$5 to \$15 per ton. In the Bullion mine the west drift from station on the 820 level of the Ward shaft is in 820 feet. The face is in block porphyry. At the Alpha shaft they are still retimbering near the 200-foot level.

ALL EXCITEMENT AT KENNEDY.—*Winnemucca Silver State*: The excitement over the rich strikes in Kennedy is increasing every day. All who visit the camp agree that it more than equals any former discovery in the State, some not even excepting the Comstock.

There have been over 400 locations made, and all that work has been done on show good healthy ledges that assay well in gold—some very high, but all good enough, with a mill near by, to work at a handsome profit. The Imperial, which was purchased by Mr. Wardner, has over 400 tons of \$30 ore uncovered that can be taken out in short order and milled at very slight expense, and the chances are that by the time that it is taken out he will have as much more uncovered, as he intends pushing the tunnels right in, and from the croppings it looks as if the ledge extends the whole distance of 4300 feet that he owns.

A REORGANIZED DISTRICT.—*Pioche Lode*: On the 21st inst., what was formerly known as Chief district was reorganized and called Panaca district. The central point is Chief mountain, which is about 16 miles south of Pioche, and the new district is about twelve miles

square. A great many mining locations have been made during the past month in that vicinity, some of them being considered very promising. The most important location and about the only one upon which any work has been done is the one owned by Lee & McGown, which continues to improve as development work goes ahead. The formation and ledges are porphyry, quartz and quartzite, being very similar to Ferguson district.

John Hues and others have opened up a splendid showing of gold ore on an old abandoned ledge near El Dorado canyon, in the southern portion of the county. The Kingman Miner says the ledge is three feet in width and a sample of the ore without cleaning gave a return of \$32.50.

The Condon mill continues to produce the yellow material, another \$10,000 bar being now ready for shipment. It is expected all the Jim Crow ore on hand will be run through by June 1st, when a final cleanup will be made.

TWO MINES BONDED.—*Walker Lake Bulletin*: Two mines in Silver Star district—the Dunlap and the Midwinter—were last week bonded to the Garfield Company. According to the agreement the company must begin work at once and work continuously on the mines. They agree to pay to the locators (Dunlap and Truman) 25 per cent of all ores extracted, and within 18 months they agree to pay \$15,000, and within six months thereafter they must pay \$15,000 more, making \$30,000 in all.

THE NEW GOLD MINES.—*Reno Journal*: George Cutting has returned from Esmeralda county, where he has been since the first of February last. He went to Douglas, in Silver Star district, the new mining camp in Esmeralda county. The mines are gold bearing and the prospects are good for a prosperous camp. Ed. Brown took a carload of ore from the Hard-scrabble mine to Taylor's mill at Silver City which assays from \$100 to \$125 per ton. Thorne and George sent over two tons of ore to Hawthorne which worked \$65 per ton in an arrastra at that place.

The mines were discovered last fall, and there are about 130 locations recorded to date, many of which are good prospects. A mill will probably be erected in the district this summer. There is plenty of nut pine wood and water enough for milling purposes in the district. Douglas, the new village which is being built in the district, is about nine miles from Soda Springs on the Carson and Colorado railroad.

Mr. Cutting says the silver mining districts of Esmeralda county furnish an object lesson of the ruin caused by goldbug domination. Villages which a few years ago were prosperous are now deserted. Fine buildings are crumbling into ruins, quartz mills are rusting, the mines deserted and desolation is everywhere. There are several silver mines which show up large ore bodies that cannot be worked at present. There is ore in Tule canyon, about 140 miles from Candelaria, that assays over 500 ounces of silver to the ton, but in consequence of the great expense of mining, hauling, etc., and the low price of silver, it cannot be worked at a profit.

ARIZONA.

BEADSHAW'S MINERAL.—*Prescott Journal-Miner*: The Crowned King mine and mill, which have been running steadily for the past five months, with a large force of men, eighty all told, and have been producing a large amount of bullion and concentrates, having made one of the most successful runs in the history of this mine, is now compelled to run on very short time on account of the scarcity of water. The test run made has proven highly satisfactory to the owners, and the work of development continues with a large force of men. A new pump is being put up at a spring above the mill. A pack-train of 20 burros is kept busy packing in wood, while the building of houses and hamlets of the miners still continues.

The old Del Pasco, now being worked by Bandedbug & York, and owned by Lester Jackson, situated about half a mile west of the Gladiator, and one of the oldest locations in this district, a mine that has produced thousands of dollars in bullion and placer gold, is now being developed by a crosscut and drift, which taps the vein at a depth of 300 feet from the surface. In the drift there is a very rich streak of ore assaying from \$200 to \$400 per ton.

Weet of the Del Pasco 500 yards is situated the Old Reliable, owned by Bashedoff & Brumier. The Old Reliable is, and has been, a famous producer. It is a large vein and a true fissure in granite. This mine is developed by a 1000-foot tunnel on the ledge, and by crosscut drifts, stopes, etc., in all amounting to 1600 or 1700 feet. The ore is free milling and runs from \$20 to \$200 per ton in gold. There are other claims on this lode belonging to the same company, and are now being prospected under the management of Mr. Liston. The property is one of the most valuable in this district.

The Wild Flower, another well developed property, belonging to the same company, is situated one-fourth of a mile north of the Old Reliable. A tunnel has been run on the ledge 1000 feet, and it shows a 14-foot ledge of ore averaging from \$7 to \$20 per ton in gold. Above this main tunnel another tunnel is being run, and it is in now about 180 feet. There are six men working in this tunnel. This tunnel has produced very high-grade ore, and there is now on the face a foot of ore that runs from \$40 to \$200 per ton in gold. This mine is provided with a five-stamp mill for the reduction of its ores, one stope, poettifice, boarding-houses, hamlets and other modern conveniences.

West of the Wild Flower one mile is situated the Sultan. This is a new mine, and only has been worked this year. It is a true fissure vein in granite, and is situated on the south side of the mountain, being the extension of the

Green Mountain mine (patented). Work was commenced on this property about three months ago, and from the grass roots there has been a continuous streak of free milling ore 12 inches wide and averages from \$25 to \$60 per ton in gold; the tunnel is in 70 feet, and the ore is improving as depth is attained. A crosscut is being run, and when it taps the ledge will have over 500 feet of etoping ground. This is one of the most promising mines in the district. There are now 20 tons of ore on the dump that will be milled next week at the Old Reliable mill. This property is owned by Ernest Arnez and M. C. Lison and is being worked by the former.

Northeast 1000 feet from the Sultan is the Green Mountain mine (patented) belonging to the Tower estate, and with H. T. Andrews as administrator. This is a property of local reputation and is developed by a 40-foot shaft and several drifts. This mine has produced very high-grade ore in former years, but is not being worked now.

West of the Green Mountain a quarter of a mile are the Admiral and Buena Vista. The Admiral shaft is down 40 feet and shows a foot and a half of ore that averages \$20 to \$40 per ton in gold. The Buena Vista is a parallel vein with the Admiral, and is a very high-grade mine. Very little work has been done on this mine; a tunnel has been run in 20 feet and shows a six-inch streak of very high-grade ore running from \$100 to \$500 per ton in gold. These properties are owned by Ernest Arnez and Monrial; development work will commence on all these mines in two weeks. Mill tests at the Old Reliable mill of these properties have proven highly satisfactory, and several cars of gold bullion have been shipped through the house of Beshford & Barnister to the U. S. Mint, at San Francisco, from these mines.

THE JUMBO MINE.—Denver Record: Three tons of ore from the Jumbo mine, Rustler Camp, Arizona, were taken to the sampling works at Mojave last week and gave a result of 18 ounces of gold to the ton. The ledge from which the ore was taken is of good width and is one of the best veins in the district. The mine will at once be opened up in a systematic manner and a mill erected. From three and three-fourths pounds of picked rock from this mine there was obtained by the simple use of mortar and pan 6½ ounces of gold, worth \$17 per ounce.

NOTHING IN THE "GRANT SCARE."—The so-called "grant scare" is not bothering the miners and mine owners of Cochiti. The Santa Fe New Mexican asserts and defies successful contradiction, that all of the best mines in the Cochiti district are on Government land and that the so-called "grant scare" was gotten up by designing persons based upon selfish motives to extort a few paltry dollars from the enterprising miner.

COLORADO.

NEW STRIKES IN COCHITI DISTRICT.—Denver Republican: New strikes of ore running from \$32 to \$100 per ton are so frequent in the Cochiti district that they excite very little comment. Returns just at hand from Burlingame show \$700 ore in a new prospect in Cella canyon. In the Lone Star tunnel a rich vein of \$400 ore has been struck and when roasted it shows blisters of gold. That the principal mines run high in tellurium is now settled beyond all doubt. A fine body of mineral, similar to that in the Crown Point, has been uncovered in the Miners' Union claim in the west fork of Pino canyon, over a mile from the Crown Point. In Cochiti canyon the Little Colorado claim, owned by La Junta parties, reports a new strike, assay returns from which have come to hand from Pueblo. It yields \$41 in gold and \$85 in silver, making a total of \$126 to the ton. Near Bear canyon, ten miles south of Pino canyon, some fine ore is being extracted, and the ledge are similar to those in the Lone Star. One claim, which shows twelve feet of quartz, gives an assay return of one ounce in gold and 3½ ounces in silver. The same croppings are found near Borrego springs, and things are lively in that locality.

IDAHO.

POORMAN.—Avanache: The rich ore in the Belle Peck tunnel continues as good as reported last week. The south drift has softened up some and the pay streak is larger. No. 3 is being driven south in rich ore. The slopes continue rich and the ore-house is kept piled full, notwithstanding the steady running of the mill. They have ore in sight to run the present milling plant indefinitely.

TRADE DOLLAR.—The mine is looking fine at every point where work is being prosecuted. The face of the adit tunnel continues in good ore as progress is made into the mountain. This chert (north of the npraise) is in the Feour ground, recently acquired by the Trade Dollar Company, and has about 800 feet of "backs." Taken with the reserves in the original group, the production from this property is assured for years to come. Four bars of bullion were shipped out on the stage last Tuesday. Some first-class ore and concentrates have also been shipped lately.

OREGON.

Jacksonville Times: Phil Miller brought in 120 ounces of gold dust from the Miller placer mine in Farmer's flat on Wednesday. They have only just begun to clean up, and this gold was taken from a few boxes, leaving the greater number and all the bedrock to be cleaned yet. The output for the season will run close to \$10,000. Swinden & Hayes cleaned up \$1200 from an eight days' run lately on their Oscar Creek placer mine in Josephine county. The Homestake mine near Woodville is developing in a promising manner. A tunnel has been run to a depth of 270 feet, tapping the ledge about 200 feet from the surface. The lode is two feet wide in the face of the

tunnel and shows high-grade ore. Fred Maher has struck what looks like a bonanza between Thompson and Williams creeks, in the shape of a two-foot ledge of gold-bearing quartz, from which he has pounded out with a hand mortar from \$2 to \$20 to the pan. It is said to be no pocket, but a true fissure vein. Operations will be resumed on the old Hope ledge in the Wagon Creek district, now known as the Shorty, in a few days. An excellent mill has been put up there. The mill at the Mountain Lion mine on Missouri flat has been shut down for reasons unknown. The tunnel is now in 300 feet, and an inexhaustible supply of rich ore is said to be in sight.

EAGLE CREEK PLACERS.—Baker City Democrat: The interest manifested by Eastern capital for the past several months in the placer fields along Snake river is phenomenal, and thousands of acres along that stream have been located and machinery placed thereon to save the fine gold found in the bare and banks.

The tide of investment has been gradually working its way Oregonward and has at last developed in this vicinity.

A Duluth, Minnesota, company, represented by Messrs. Joseph McAfee and Frank Merritt, have located eight miles of Eagle creek, Union county, commencing at a point known as Sbanghi Falls, a few miles from Sperts, and running up stream. The enterprise is one of large proportions and will require the outlay of considerable money. Mr. McAfee estimates that upward of \$75,000 will be expended in machinery and in putting in a bedrock flume to work the mines.

It has been known for many years that the bed of Eagle creek contained gold in large quantity, but owing to the huge boulders to be encountered, the undertaking was too great for people possessed of limited capital. However, the bars of the stream have been worked at intervals with good success. The improvements in machinery in latter days has given an opportunity for all obstacles to be overcome.

MONTANA.

ELLISTON DISTRICT.—Anaconda Review: The Telegraph mine is one-half mile west of the Bullion mine, which is located at the head of Bryant gulch. It is a gold property, the ore being free at the surface, but at the depth of 30 feet it is telluride gold. There is a mill on this property, which was put up several years ago, but as the character of the ore changed and it became base, of course the mill ceased to be a success and has been idle since. The lead is an immense one, 46 feet wide. There are about 200 feet of shafts on the lead, and some 400 feet of tunnels run. There is an open cut from the mill stripped off from 32 to 50 feet from the face. The ore, like that of all similar mines is low grade, but there are some very rich spots in it. The mine has been bonded for a time, which may account for the property having been allowed to remain idle so long.

It is stated that the ore can be mined and placed in the mill for the exceedingly low sum of 28 cents per ton. The mine was discovered by tracing up the source of rich placer diggings that were in the gulch below, and in going up the hill a little higher the lead was encountered. The mine is the property of John Ashley & Co.

The Bullion mine is developed by a perpendicular shaft to a depth of 250 feet, and has been worked several years, the ore being treated at Remeni. The past year and a half it has not been worked, owing to the low price of silver. It is low grade, but there are large quantities of ore. The mine is owned by William Cranich and A. M. Holter.

The Ontario is a silver and gold proposition that is very much thought of in this district, and it is now being worked steadily. A new concentrator has been erected on this property, and it has proved a great success from the start. The concentrates are being shipped to Tacoma for smelting. The mine is considered a very valuable one.

On "Nigger hill," seven miles southeast of Elliston, there is also a very promising district.

The Mountain View is developed by a main tunnel in about 250 feet, and from this there is a 30-foot winze, below which there are fully 800 feet of tunnel work. The ore is mainly lead and silver, though it carries about \$4 in gold to the ton. The company has out on the dump about seven cars of ore ready for shipment. This mine is owned by Frank Taylor and William Budgeon.

The Bob Tail is another silver property, of somewhat higher grade than the Mountain View. It has one shaft that is down 35 feet, and another one 65 feet, with about 150 feet of tunnel work. The vein is about four feet thick. The percentage of gold is considerably higher than that of the mine previously mentioned. The owners are Tom Porter, Gne Thornton and Chas. Lindley.

The Big Dick is another exceedingly promising property. It is developed by a shaft down 150 feet, and a mill run from a car of ore realized \$100 to the ton for the fortunate owners, who are a stock company.

The Comstock is another paying institution. It is developed by a shaft down 106 feet. A mill run from this mine of a car of ore realized \$96 to the ton. This was handled at East Helena.

SOUTH DAKOTA.

THE CYANIDE PROCESS.—Deadwood Pioneer: The cyanide process, as handled by the Gold Recovery Company, of which J. S. Childs and Dr. Taylor are the heads, has been proven beyond a peradventure to be a great success. Yesterday's cleanup resulted in a bright yellow brick weighing 95 ounces, valued at \$1900. This brick was the product of 85 tons of ore from the company's property at Blacktail. The ore averaged \$25 per ton. This shows an extraction of a little over 90 per cent. It is one of the most satisfactory cleanups ever made at this plant. The cleanups made prior to the re-

jection of the Morrell pulverizer showed as high as 84 per cent by extraction. But now, since the plant has been fitted with finishing rolls in place of the pulverizer, the crushing of the ore has been gotten down to a science and the percentage of extraction has been increased and the working of the plant greatly facilitated. In cyanide the problem of treating the low-grade ores of the Hills has been found. Not that the process is cheaper than any other—we think it is, though, but in that it saves a higher percentage of the metal contained in the ores. In chlorination we understand the cost of reduction per ton is \$2.77 with an extraction of 75 per cent. Pyritic smelting costs per ton \$3, and as high as \$5, per ton, extraction 78 per cent. Free-milling ore reduction by stamp mills, 88 cents per ton, when handled in quantities such as the Homestake handles it, saving in extraction from 65 to 78 per cent; average saving, 68 per cent. Cyanide, cost of production per ton, \$3, per cent of extraction, 90. The success of the cyanide process shows its adaptability to the ores of this section. The ores which have been treated at this plant can be termed representative ores of this district, or at least the district covered by the blanket or flat formation, which is of a refractory and very rebellious nature, and heretofore only susceptible to the chlorination and smelting processes. The operations of the cyanide plant since its resumption have not been experimental runs—the days of experience being long passed by—but runs made with understanding that the process was a success and doing the work for which it was intended, as demonstrated by the experimental runs of long ago.

UTAH.

MINING MATTERS QUIET.—The past week has been another quiet one among the mines of Utah, says the Salt Lake Tribune. They are all working in a desultory way—in fact, they are just holding on. The silver mines are working and the owners are waiting for a better price for silver. The quotations of silver have been about the same all the week, the latest being 62½ cents.

There is still some activity among the gold camps, but little of special interest is going on.

A good many men are employed in doing development work at Mercen, and the claim-owners are as confident as ever that that district is destined to be one of the greatest gold-producers in the world.

There were no sales of Utah stocks reported on the New York Board last week.

Coast Industrial Notes.

—It is proposed to establish a State Ice manufactory at Folsom prison.

—The Great Northern is preparing to put a line of steamers on Puget Sound to compete with the Northern Pacific.

—The Royal City, B. C., Planing Mills were totally destroyed by fire last Saturday; loss \$100,000, insurance \$75,000.

—Representative English says he is confident that he will succeed in his efforts to secure a duty of five cents per pound on quicksilver.

—The South Bend, Wash., Sawmill has been purchased by John S. Harris, a representative of the Weyerhaeuser syndicate of Wisconsin and Minnesota.

—The Tacoma Match Works recently shipped two carloads of Tacoma-made parlor matches to Chicago. No other parlor matches are made west of the Mississippi.

—The last wheat cargo of the season has gone to Europe. The sworn value was the unprecedented figure of 54 cents a bushel—90 cents a cental—something before unheard of in California.

—The present relation between supply and demand in the lumber business is exemplified by the fact that while the 250 shingle mills in the Northwest have a combined cutting capacity of 18,000,000 shingles daily, the average present monthly shipments do not exceed 100,000,000.

—The new cruiser Olympia, being built by the Union Iron Works, is nearly finished, and is now lying alongside the company's docks waiting her battery. The turrets are as yet unarmored, but it is thought the delay will be but temporary. That is something that rests between the Government and the Eastern firm that furnishes the plates. The vessel is a splendid advertisement of the skill and enterprise of its California builders.

—Fish Commissioner Crawford of Washington has furnished the following statistics of the fishing industry of the State: Fishermen were paid by Washington canneries five cents a pound for salmon; the catch amounted to 6,721,435 pounds. They also sold to Oregon canneries to the value of \$150,000. The value of the spring pack of the Washington canneries for 1893 was \$790,432, and of the fall pack, \$35,000. The amount received by Washington fishermen on the Columbia river for 1893 was \$626,071. The sturgeon catch was valued at \$52,635. The Gray's and Willapa harbor fishermen were paid \$23,439 by the canneries and sold elsewhere salmon to the amount of \$11,000. The value of the salmon pack in the Puget Sound district for the same time was \$269,000.

The Advantages of an Earth Battery.

In view of the dangers which threaten the city through the destruction of the gas and water mains caused by electrolysis, a recent practical test of the relative strength and durability of the ordinary cell battery and Professor Michael Emme's Ground Generator is especially interesting. One of Professor Emme's generators was placed in a vacant lot on Sacramento street, near Prof. Price's laboratory, on the 16th inst., beside a cell battery of equal power—½-horse power—and each was connected by wires with electrical instruments located in Prof. Price's office, upon which the tests were made. Prof. Price has kept a careful record—reading the instruments each hour during the day—of the exact amount of electromotive force produced by the ground generator in comparison with the cell battery. This test was deemed necessary because of the assertion, frequently made, that the earth exerts no real influence upon the Emme generator—that if the zinc and carbon plates were put into ordinary cells, in an acid solution, the result would be the same. This assertion has been disproved in a signally convincing manner. While the ground generator is still developing its full force of ½-horse power, or 93 watts, the cell battery began to fail within two hours after both were started, and within 24 hours was giving but four watts—barely energy enough to turn a small motor. In six days the cell battery was exhausted, and had to be replenished and repaired three times—120 gallons of depolarizing and exciting fluid producing full power for but three hours. The cell battery is now dead, while the ground generator is as active as at the beginning of the test.

Up to this time the latter has required but 18 gallons of depolarizing and five gallons of exciting solutions, and no stoppage for repairs or from any other cause has been necessary. In other words, the ground battery continues, and will continue to run steadily, with full power, until the zinc plates are entirely consumed, but a few minutes' attention each day being required for it. Though the same number of zinc plates are used in each, with a difference of but 8½ pounds' weight in favor of the generator, the latter occupies but one-third the space required for the cell battery. Professor Price has made two other tests, viz.: electro-metallurgical deposition of copper as compared with a dynamo, and also a comparison of electric lighting between the two systems. The result of these experiments showed, when the zincs were weighed this morning, that the Ground Generator lost 4½ pounds of zinc in ten days' constant running day and night, against 88½ pounds in the cell battery.

These and the tests above mentioned, which have been carefully watched by numbers of practical men—electricians and others—should be conclusive (really they are so) as to the relative merits of the cell battery and the ground generator, forever setting at rest all doubts as to the efficiency and economy of the latter.

It is of interest just now to know that Professor Emme has discovered that electric currents can be transmitted through a naked copper wire placed under ground, dry or wet, without what electricians call dissipation of electricity, and without loss except ohmic resistance of wire and lead. Professor Emme claims that the two wires, positive and negative, will be perfectly protected from electrical action between them, and that no green oxide of copper will form on the positive wire. He has had similar wires under the ground fourteen months, and they are still in perfect condition. This discovery will enable the use of an underground system of transmitting electricity for electric railways, and thus obviate the dangers that now threaten gas and water pipes, while doing away with the unsightly and dangerous trolley system. The ground generator system may be seen daily at 524 Sacramento street.—S. F. Report, May 26th.

Market Reports.

The Markets.

SAN FRANCISCO, May 31, 1894.

But little movement was observable during the week, silver remaining about the same.

Mining Share Market.

SAN FRANCISCO, May 31, 1894.

Memorial day holiday made some difference in this week's market, and the absence of definite news from the present center of interest—the 1650-foot level of the Con. Va.—contributed to quietness. There was a little stir in Gould & Curry, but everything was played with a very light limit.

The following illustrates the changes of the week:

Archibald Forbes' Battle Picture from the Next Great War.

Let me briefly adumbrate the possibilities—indeed, I may say the probabilities—of the results of a great battle in the next great war, which is sure to be "short, sharp and decisive." The fighting has been prolonged and bloody, with the result that one side is definitely beaten, evacuates its positions and retreats more or less precipitately, leaving on the ground its wounded, none of whom could be cared for while the conflict lasted. The successful commander's ground is littered with his own wounded; he has them on his hands in thousands, and he has also on his hands the thousands of the wounded of the vanquished force which has gone away. The conqueror of the future, if he accepts the old-time conventional burden of his adversary's wounded, will become its victim. He will not accept the incubus. Is it to be imagined that the victor in such circumstances will think twice even about his own wounded, let alone the wounded of the other side? No. He is in the field, not to be a hospital nurse, but to follow up his advantage by hammering on the enemy who has departed, leaving his own wounded behind, and who may come back again to-morrow to strike him while clogged in the live and dead debris of yesterday's battle. The victor will hasten away to overtake or hang on the skirts of the vanquished army, leaving the wounded of both sides to be dealt with as may be possible by such surgeons as he can afford, in view of future contingencies, to leave behind, and to the ministrations of cosmopolitan amateur philanthropists of the Red Cross and kindred organizations. For there will be no more military hearer companies; in the hunger for fighting men, the 1000 hearers per army corps of the present will have been incorporated into a strong brigade with arms in their hands and a place in the fighting line.—Scribner's.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market Street.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

—Organization has been completed of the Portland, Vancouver and Northern Railway Company, with a capital of \$3,000,000, to build a road from Portland to the Northern Pacific at North Yakima.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower engine and 45-horsepower boiler, with Ore-crusher and other machinery, Mill Scales, Assaying outfit, etc., all newly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1214 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep places, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hardy-gurds, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and duty of miners; inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

MINING SHAREHOLDERS' DIRECTORY.

GOLD EXTRACTION EXTRAORDINARY!

Two Improved Crawford Mills have treated about one thousand tons ore at the Columbia Mine, Moore County, N. C., capacity of each mill being over 10 tons daily, and the cost of wear and tear 20 cents per ton. On a formal trial run of 100 tons, 84 per cent of ore's value was cleaned up in gold, exclusive of some rich concentrates produced by mill. Three additional Crawford Mills have been added to plant at this mine.

CHEAPEST AND BEST MILL IN THE MARKET.

MECHANICAL GOLD EXTRACTOR CO., 47 Broadway, New York.

W. O. ROSS, Sec'y and Treas.

Van Drake & Taylor, MACHINISTS AND MECHANICAL ENGINEERS

523 & 525 Mission St., San Francisco.

SPUR AND BEVEL GEARS cut to order.

PATENT MODELS and Experimental Machinery of all kinds.

SHAFTING, PULLEYS and BOXES.

ENGINES and BOILERS.

DRAWINGS, PLANS and SPECIFICATIONS made for new machinery.
 JOBBING of every description promptly attended to. FINE WORKMANSHIP GUARANTEED.
 Also Pacific Coast Agents for the SHARLES CREAM SEPARATORS.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outfit one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clock changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clock cannot be changed under water. The self-lightening and self-lubricating stuffing box and new bucket also save expense of dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, California.

The Explorers' and Assayers' Companion.

Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

EASTERN PRICES BEATEN.

San Francisco Pioneer Screen Works

JOHN W. QUICK, Proprietor.

IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.

Perforated Sheet Metals, Steel, Russia Iron, American Planish, Zinc, Copper and Brass Screens for all uses.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstract calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. True the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is especially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:
 General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae; Oblique; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Opening; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Table of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend-Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.
 Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l Supt. FRENCH GULCH, Shasta Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWENTY MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

WARNING.

Many so-called gasoline engines are now on the market which are direct infringements on our patents and it is our intention to bring suit against the various infringers. As the law holds the purchaser, as well as the manufacturer, we would advise parties who have already purchased other gasoline engines to obtain from the sellers of such engines A GOOD AND SUFFICIENT BOND PROTECTING THEMSELVES IN CASE DAMAGES ARE OBTAINED AGAINST THEM, as it is not the policy of this company to work a hardship on innocent parties, but the law makes no such provision.

Pelton Water Power Hoist.

The illustration herewith shows a water-power hoist of recent and modern construction, embracing all the safety appliances and improvements in this class of machinery. The design presented is a flat-rope double-reel hoist for a two-compartment shaft, recently built by the Pelton Water Wheel Co. for the Milwaukee mine in the Cœur d'Alene district, Idaho.

The wheels are six feet in diameter, made of solid steel discs with phosphor bronze buckets, and run under 850

work to a depth of 1000 to 1500 feet. The gearing can be arranged to increase the speed to 600 feet per minute if desired. A three-fourths inch stream under head named gives each wheel a capacity of 70-horse power and a one-inch stream 120-horse power. Similar hoists with reels for both flat and round rope have been furnished by the Pelton Company to many of the most prominent mines on the coast, some working to a depth of more than 2000 feet. The wheels and appliances connected therewith, constituting the power part of the plant above described, weigh only 2800 pounds, thus indicating the great advantage of water

THE prevalent dullness has had no apparent effect on the sharpeners who prey on honest industry. Just at present inventors seem to be considered as good game to go after. The latest is for some "patent firm" in Chicago, for instance, to secure the names and addresses of people taking out patents, and write, telling the inventor or assignee that he has a "good thing," and that in all probability the patent could be traded for a farm in Iowa, incidentally mentioning that it would cost \$25 "to examine the title." Farms in Iowa are good things, if big enough and fertile enough, but it transpires, very singularly, too, that in

PELTON WATER POWER HOIST.

feet head at 375 revolutions, which gives the wheels a peripheral velocity of 6800 feet per minute. Water is applied to the wheels through nozzles, the gates of which are controlled by hydraulic valves operated by levers at the engineer's stand. An air receiver is located at the lower end of the pipe to prevent a shock to the line by a sudden closing of the gate. The nozzles are provided with deflectors operated by levers which give the engineer control of the wheels independent of any movement of the gates, admitting of their being stopped instantly in case of accident.

The hoist is equipped with powerful post brakes operated by foot treadles, which afford absolute security in stopping or lowering the cages, and give perfect control of the movement at all points in the shaft, while to afford additional security the wheels may be instantly reversed without shock or injury by applying the stream in an opposite direction. The reels are mounted on separate shafts and connected by gearing and clutches on pinion shaft so that they may be operated together or independently, as may be desired.

The hoist here referred to is designed for carrying a load of 5500 pounds at a speed of 400 feet per minute and

power whereby any reasonable means it can be made available.

It is certainly true, says *Iron and Trade Review*, that the manufacturers who have pushed hardest for business in the months of depression are the ones who have had most to do. On the other hand, those who have made little effort to get orders, on the assumption that "nobody has any money to buy anything with anyhow," as we have heard some lackadaisical people put it, have been taken at their word. If it is true in any line of activity that "all things come to him who waits," the aphorism has no truthful foundation in the world of business.

THE following homely bit of good advice to Arizonians is from the *Prescott Courier*: "A prospect is not a mine; it is just as reasonable to demand \$50,000 from an intending purchaser for an unborn blooded colt as to ask him \$50,000 for a little hen-scratching on the surface of the ground which may give birth to a mine, if the mine don't 'die a-bornin'.' Be reasonable, gentlemen; money is scarce, and many of you who would not sell for less than half a million could not count that sum of money if you were going to be hung."

every case where the \$25 was sent, the title to the farm was, somehow, defective, and the money was lost. 'Tis reported the men who worked this scheme have made \$30,000 out of it. Of course, publicity is fatal to such frauds, and their occupation will soon be gone.

AMONG other industries in this city is the sale, principally to Chinamen, of Mexican dollars, freshly coined, at fifty-two cents each. The dollars are good in China. It is a transaction in which, ultimately, the country loses forty-eight cents. The conditions that make such trade profitable or possible are in opposition to our country's interests. In this general loss lies largely the reason for existing depression. Upon the correct solution of the problem depends largely the return of healthy financial conditions.

STATISTICS of issuance of patents give suggestive comparisons. In '92, 2122 patents were granted to residents of Massachusetts; 49 to residents of South Carolina; 3907 to citizens of New York; 3 to Wyoming; in Connecticut one patent was received to every 1018 people; in Mississippi, one to every 20,000; in California, one to every 1900; in North Carolina, one to 21,000; in Illinois, one to 1900.

 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 365-366.

COUNTERFEIT American silver dollars are now being made in Mexico, sent to England in payment for British exports to Mexico, and, it is said, thence shipped by English merchants to this country, where they are circulated at 100 cents. The thing is possible: more difficult things have been done.

The *Industrial World* is worrying itself about what it calls "the fresh gold mining craze." There is nothing fresh about it nor nothing crazy. The impetus is toward an industry that is never overcrowded, that is always sure of a good market for its product, that cannot suffer by competition nor depreciate in value. That is all there is to it, and it is as natural as the instinct of thirsty men for a drink.

It is considered certain that in less than a hundred days electric power generated at Niagara Falls will be delivered in Buffalo, N. Y. The current will be raised at the tunnel to a potential approximating 30,000 volts and carried to Buffalo by underground wires, where its potential will be reduced and operate motor dynamos at a cost, it is said, of two-thirds the present cost of steam power.

CARSON, NEV., fears that it will lose the mint and that that government institution will be removed to Denver. Director Preston favors such action and also favors certain modifications regarding the Philadelphia mint. Waiving all discussion of the matter, it is manifest that the protest that will go up from Pennsylvania regarding the Philadelphia mint will block the movement, and, incidentally, discount all probability of the removal of the mint from the Nevada capital.

THE question of what constitutes "raw material" is an important one to the firm of O'Connell & Lewis of this city. They secured a contract to build a dome on the New City Hall for \$249,000, it being expressly agreed that all material used must be of California manufacture. Were Eastern material allowed the contract could be made for about \$20,000 less. The city's architect and superintendent of construction, discovering that the steel blooms used by the Judson Iron Works in Oakland were shipped from the Carnegie works in Pennsylvania, refused to accept any work containing the Pennsylvania material. The contractors say that the article is "raw material," and not a manufactured article. The City Hall Commission deny the claim. By strict construction of the terms of the contract, the firm will have to discard the Pennsylvania article. The exact status of "raw material" is sometimes a hard question to satisfactorily decide, so much depending on the point of view as well as the facts. For instance, a woolen manufacturer claims that wool is "raw material," while the man who raised the sheep and sheared the fleece claims that it is a finished product.

Half a Loaf.

At present writing the tariff bill in the Senate reduces the duty on lead from \$30 a ton to \$15—just one-half. As originally reported from the House, lead was on the free list. Under the McKinley bill, foreign lead in pigs or ores was taxed one and one-half cents per pound. That enabled mine-owners to pay at least two dollars a day. Evidently the House of Representatives thought this was too much for an American miner to get, so, to give the Mexican two-bits-a-day laborer a chance, lead was made free. This, of course, would shut down every lead-producing mine in the Union. Folly could no further go. A glimmer of sense in the Senate has put the duty back at half the former rates. A full understanding of the requirements of the situation would put the duty at the old figures—thirty dollars a ton. It is unfortunate that the mining industries of this country and the very lives of the men engaged in mining should be thus made the sport and football of men who accidentally find themselves in a position to put American workmen on a level with Mexican peons. The whole thing is a badly mixed mess, and no one in or out of Congress can tell what the result of all this costly folly will be. When the Senate does finally get to a vote, in the event the bill in its present shape passes, it will go back to the House and be again an opportunity for further demonstration of the fact that the only reason sundry misfits in the lower house do not make fools of themselves is that Nature denied them the opportunity.

Not a Good Proposition.

As the Midwinter Fair draws to a close, the question arises, "What shall be done with the buildings?" The Executive Committee are under agreement with the Park Commissioners to destroy and remove all the buildings immediately after the fair closes, but some of them, especially the Administration and Fine Arts buildings, could well be retained. Their solidity and beauty justify their retention.

In this regard it has been suggested that the California State Mining Exhibit, now located in Pioneer Hall, on Fourth below Market street, be transferred to the Fine Art Building. To the MINING AND SCIENTIFIC PRESS it would seem to be a great mistake to think of such a thing. The present location of the exhibit is not the best; there are many and valid objections to having it where it is; but to move it away out to so remote a suburb of the city would be to greatly destroy its usefulness. The value of such an exhibit rests largely on its convenience of access. It ought to be as near the center of the city as possible; close to the hotels, near where mining men mostly congregate, and to relegate it to a lonely nook in the park would be a mistake. If any move is made it should be to put the exhibit in a more central location than at present. It is to be hoped that the suggestion of the Executive Committee will be negated. The motive is evidently kindly and the proffer is courteously made, but the best interests of the exhibit and all it represents suggest that the offer be declined.

The Nicaragua Canal.

At the meeting of the Pacific Coast Technical Society on the 1st inst., Wm. Sherwood read a paper on the Nicaragua Canal. He was one of the assistant engineers on the ground, and has a personal and practical knowledge of the matter. According to Mr. Sherwood's statements, matters are in a bad way. He said that there are difficulties and objections not understood by any one who has not visited the locality. The heavy rains, the swampy land, the dilapidated condition of the machinery, the unhealthy climate, the scarcity of labor, the lack of construction material, make the feasibility of the undertaking very doubtful, according to Mr. Sherwood. His remarks indicated that he was actuated more from a desire to state facts of which he was personally cognizant than to create any adverse feeling for interested motives. He drew a very gloomy picture of the enterprise in its present condition, very discouraging to all well-wishers of the enterprise.

The fact that Mr. Sherwood had been engaged as civil engineer there, and was stationed there some time with ample opportunity for impartial observation gives value to his assertions.

It is to be hoped, however, that the picture is overdrawn. The canal is a necessity to the interests of the Pacific Coast, and, with the indomitable spirit of American enterprise, the greater the obstacle the greater the incentive to overcome it.

Every railroad interest in the country opposes the canal, thus constituting a very formidable menace to the enterprise, but paramount to all that are the interests of the

nation, which are closely allied with successful prosecution of work on that great waterway.

Lieut. Menocal of the U. S. N. has been before the House Commerce Committee this week in an endeavor to push the proposition. He thinks the work can be done for \$60,000,000, and that it could be completed in six years.

T. S. Atkins, the New York receiver of the Nicaragua Canal and Construction Company, sold at public auction last Tuesday all the property and assets of the company for \$297,625.

Better at Home.

Probably few who are going, or thinking of going, to South Africa realize the fact that there is a thousand times more gold in California than was ever taken out. The only advantage, if advantage it may be called, that South Africa has is that it is comparatively a new country. But California is, in one sense, an undeveloped country: as undeveloped as South Africa. Were California just discovered there would be a "rush" to the Sierras and the foothills, for, as a rule, the less that is known of a region the greater the excitement. Fancy takes the place of fact.

Without assuming to decry other localities near or far, it is a demonstrable fact that California's contribution to the world's treasure has been only what was picked from the surface. The storehouse itself has scarcely been unlocked.

This is not written in depreciation of the spirit of adventure that impels energetic men to go to fields afar—the farther the more inviting. They will mostly return wiser, and it is hoped richer. It is said simply to assert what is not widely understood—that from one end of this State to the other lies a vast deposit of gold, as yet only scratched a little on the surface. The crude appliances of the early days, clever inventions born of necessity and new conditions, are being supplanted by scientifically constructed machinery, and while that which was easiest reached is not by any means exhausted, the deeper gravel deposits and the quartz ledges will, under the new and improved methods, yield rich return for ages to come.

Mining, like other things, is becoming systematized; it is now being put in business form, and invites the attention of dividend-desiring capital the same as any other legitimate, safely conducted business.

Since the above was in type the following appears in the *Bulletin* of this city, which bears on the same general subject:

"We make a mistake in going to England for mining capital," said W. S. Chapman to-day in talking about gold mining in California. He has had many years of experience as a mining man, and is thoroughly acquainted with the mineral districts of the State.

"Yes," continued Mr. Chapman, "our own people should be the ones to develop our mines. If foreign capital is put in, foreigners are going to get the profits. Mining in California is to-day the best and most profitable business in the world when systematically conducted by men who understand it. But not every man makes a good manager of mines. It takes much experience and sound judgment."

"Do I think gold mining is likely to increase in California? Most assuredly. There is much talk about the African gold fields just now, but let me tell you that in California we have the best and most extensive gold fields in the world. Most of our old mines that were once thought to be worked out are in reality undeveloped and may yet produce handsomely. In the past eighteen months Mr. Hayward has opened up five such mines that are paying well. Do you know that the Ulica mine, in Calaveras, the principal gold producer in the State, was some years ago sold for \$1000, the owners believing it was worked out? And now it is valued at not less than \$3,000,000. They are down only about 500 feet in that mine, and it probably has a great future."

"I could mention many such instances. In the early days mines were often abandoned when the water level was reached or the water troublesome to handle, or when a pay chute was worked out. The expense of working was vastly great in those times, and there was lack of the improved machinery and facilities for developing power and draining mines that are now at our disposal."

"The great mother lode, or productive zone or belt, running along the western slope of the Sierra Nevada, from end to end of the State, and into Mexico, abounds in mines that are yet to be opened. It has scarcely yet been prospected. And in the deep gravel deposits, likewise, there are untold millions in gold that will not be exhausted for centuries to come. Gold mining in California is still in its infancy."

"Do you believe in the theory that the deep gravel deposits lie in the channels of ancient rivers?"

"I do not. The theory does not fit all the facts. Take, for instance, the Thistle drift mine on the Gibsonville ridge, in Sierra county. A Scotch company has been profitably working that mine for several years. The gold is found in coarse gravel and boulders on the bedrock, in a channel hundreds of feet wide, and with a fall of seven feet to the hundred. The ancient deposit is from 50 to 109 feet thick under the superficial lava formation, and contains much sand and small gravel. Had that channel been occupied by a river, the velocity of the stream, with such a slope, would have swept out all that sand and gravel in half an hour."

"But it is of no practical consequence how the gravel got there. The miner deals with the facts as he finds them, and he knows that there is plenty of gold in the coarse material on the bedrock. The problem is to get at it, and to drain the channel. This may be done by a tunnel, or by a shaft, with pumping."

"The country about Oroville, and at other points along the great range, covers vast deposits of gravel rich in gold. I have never seen the Magalia mine that it is now proposed to reopen, but know of it by reputation as a large producer of gold under past workings, and see no reason why it should not again yield well. There is bound to be a great development of drift mining, and it is not unlikely that our drift mines will ulti-

mately yield as much annually as our quartz mines. This is because it is relatively easier to get at the gold in the gravel than in the lode. Both sources of this precious metal are practically inexhaustible.

"There never was a time when there was more inquiry for California gold mines, as permanent investments, than there is now. People who used to think gold mining a speculation are finding out that it is a legitimate and safe business, when conducted on sound principles and with due caution."

Mr. Chipman's citing of old mines reopened and reworked at great profit illustrates the statement made. Because a mine is idle or abandoned does not argue against its value. Probably all that it needed was capital or a little stick-to-it-iveness, or both. Many an idle or forsaken claim holds great wealth for its developer.

It would, of course, be better to have our mines developed by home capital and have the profit retained at home, but it would be better to have mines being worked by foreign capital than to have them idle or undeveloped. The majority of mines employ a good many men and buy large quantities of supplies. The next best thing to having money one's self is for some one else to have it.

A Valuable Gold Mine.

The Alaska Treadwell Gold Mining Company of Douglas Island, Alaska, has declared a bonus dividend of 75 cents per share, or \$150,000, payable next Monday, the 11th. The Treadwell mine originally cost the man after whom it is named \$150. About \$800,000 has been spent developing the mine; \$300,000 was spent experimenting with chlorination. About 600 tons of ore is milled daily, at an average cost of \$1.25 a ton. The ore averages in value three dollars a ton. The company is said to have refused \$16,000,000 for the mine. It is thought that there is nearly \$25,000,000 in sight.

Clipped and Condensed.

THE United States revenue cutter Bear is reported a total loss off the entrance to Sitka, Alaska, all hands saved.

Oregon elected last Monday an entire State and legislative ticket by an average Republican plurality of 10,000.

EASTERN manufacturers of fire arms are unable to keep up with orders from the Pennsylvania coal mining districts.

It is thought that the losses throughout the country during the last few weeks by violent floods will aggregate \$20,000,000.

The California commissioners to the Chicago exposition will have \$20,000 left to turn into the State treasury after paying all bills.

A BILL has been beaten by a decisive majority in the House of Representatives looking to the re-introduction of the old State-bank issue of currency.

COLLISIONS of strikers and other armed men are of daily occurrence in the bituminous coal regions. So far the strikers are successful and defiant.

It is stated in Washington on high authority that the statements regarding another bond issue in contemplation are absolutely without foundation.

The total coinage of the mints of the United States during May, 1894, was \$9,120,450, of which \$3,445,450 was gold and \$5,675,000 was silver. The silver coinage was entirely of half-dollars and quarters.

The New York legislature has passed a bill abolishing the customary three days' grace in the payment of checks, drafts, etc. The American Bankers' Association is trying to have similar action taken by all the State legislatures.

JAS. W. HAAS, formerly postmaster at Mineral Park, Arizona, has been arrested charged with opening registered letters; two letters passing through that postoffice to El Dorado Canyon had been opened and \$500 in currency abstracted.

THE report of the Suez Canal Company shows that in 1893 its revenue amounted to 75,579,992 francs, and the expenses, including five per cent interest, amounted to 36,964,455 francs. This leaves a profit of about 40,000,000 francs, giving a dividend of 72 francs, which, added to the five per cent interest, makes 79 francs per share.

FOURTY years ago the present Lord Roseberry, then a boy of 17, is reported to have declared that he would marry the richest heiress in England, become prime minister, and win the Derby. The first and second he accomplished. Last Wednesday his horse Ladas won the Derby, and Roseberry took it as a premonition, he being a prophet with honor in his own country.

THE American archaeologists who went to the recently discovered deserted city in the Sierra Madre mountains have found another hidden city five Spanish leagues north of the first. The leader, C. W. Penlon, interviewed at Mapimi, Mex., says these cities were evidently twin capitals of a wealthy district long before the Aztecs. The two are connected underground by passages hewn out of the solid rock.

ATTORNEY-GENERAL OLNEY has filed against the estate of the late Senator Stanford a claim in behalf of the United States for the sum of \$15,000,000, that being the proportionate share of the debt of the Central Pacific Railroad that estate owes the Government under the theory that the personal assets of the individual members of the original Central Pacific syndicate are liable for the debt of that corporation due or to become due to the United States.

THE floods in Colorado have occasioned widespread disaster, the greatest damage being around Pueblo. It is reported seven lives were lost. Boulder also suffered, the losses in that vicinity being estimated at \$500,000. Crisman and Selina, two mining camps in Boulder canyon, were swept out of existence. British Columbia has also suffered. The Fraser river is six inches above the highest historical mark and the Fraser valley for over 100 miles is devastated. It is estimated that over 2000 families are homeless and the property loss is \$3,000,000.

Concentrates.

So far, this has been the rainiest June in the history of the State.

THERE are 110 men on the pay roll of the Congress mine near Tombstone, Arizona.

THE smelter at Tucson, which cost \$15,000, was recently sold at sheriff's sale for \$1200.

THE Crescent and Murphy mining districts, in Lincoln Co., Nevada, have consolidated.

THE Great Western Quicksilver Mining Company of Napa is putting in new and improved machinery.

NEARLY 20,000,000 in gold left this country for Europe during May, and the nation is not on a gold basis yet.

THE Bald Eagle Mining Co. has incorporated in this city with \$100,000 capital, of which \$50 has been subscribed.

THE Davidson mine on Missouri Flat, near Grant's Pass, Oregon, is digging out a rich pocket which pays \$24 a day to the man.

SAYS the Denver Mining Review: The gold miner is now the only person who is sure of a market for his entire production at the highest known price.

THE Brunswick shaft, near Grass Valley, is to be sunk another hundred feet by contract, this work making the mine 800 feet in depth when completed.

THE Western Federation of Miners' Union, at the Salt Lake, Utah, meeting, endorsed the action of the striking miners at Cripple Creek and the Comr d'Alene.

EASTERN WASHINGTON and western Idaho miners have memorialized Congress to pass a law suspending assessment work for '94, similar to the law passed for '93.

THE Granite Pay-Streak ecstatically declares that "Leadville should change its motto from 'the greatest silver-mining camp on earth' to 'the greatest gold-mining camp on earth.'"

THE Boston & Montana Mining Company has declared a dividend of \$1 per share, payable on the 28th inst., the first since the reconstruction of the works was begun three years ago.

THE Grass Valley Telegraph would not advise any one to go there to seek employment, and says the mining superintendent is "struck" dozens of times per day by parties wanting work.

THE Honss Committee on Mining has authorized Chairman Weadock to favorably report one of the several bills to extend for one year the time of perfecting mining claims under the statute.

A MINING district which will be known as the "Mud Hills" district has been formed. It lies about 22 miles southwest of Vanderbilt and three miles west of Government Wells. Alex. Carlisle is the recorder.

THE Bankers' Mining and Milling Company, with its main office in Newark, New Jersey, is organized with \$250,000 capital, to carry on the business of mining and milling ores in Colorado, California and Nevada.

A COMPLAINT has been sworn to in the Justices' Court at San Jose charging C. A. Stockton, president and manager of the Standard Gold and Silver Mining Company with having forged the name of H. C. Morrill and Tyler Beach to a note for \$250.

THE Superior Court has ordered that the Idaho Mining Company be dissolved. Thus, says the Grass Valley Union, the company as a corporation which owned the famous old mine with a record of having produced nearly \$13,000,000 goes out of existence.

THE recent appeal for funds to continue the State mining exhibit at the fair during the month of June has been of a result sufficiently satisfactory to warrant the Executive Committee of the State Miners' Association in keeping the exhibit open till the close of the Exposition.

THE Sahjuauro Mining Company has incorporated with a capital of \$500,000, fully subscribed. Directors—Hamilton W. Gray, Henry Gray, E. H. Brandt, George Heazleton, John Finlay. The two first named directors subscribe \$249,850 each toward the capital stock.

THE Phoenix, Arizona, Gazette claims that during the last year Arizona has made greater progress in the output of gold than it had in the previous ten. Present estimates for 1894 are in the neighborhood of \$5,000,000, and if this is reached the Gazette predicts that the amount will be doubled next year.

ALL treasure from the Angele mines will be shipped via Valley Springs hereafter instead of by way of Milton. The Ledger says this change has been made as the Milton route is the popular one for travelers, and since highwaymen have become so numerous and daring a large number of people travel by private conveyance.

THE Nevada City Herald thinks that if our great mining men who are now flocking to South Africa to seek investments would look nearer home for the same, they would not only find large and paying gold properties enough to satisfy the most ambitious, but would have the advantage of living in a white man's land.

THE Leonard mine has been sold for \$6000 cash. According to the Calaveras Citizen, a force of men are already at work running a tunnel and widening the road to haul in machinery, and a ten-stamp mill will be erected on the ground immediately. This is the property managed by W. S. Weymouth of Drytown for the Crocker of Fitchburg, Massachusetts.

THE Virginia Enterprise says that during the past six months many new and valuable gold discoveries have been made in Nevada. The new finds have been made principally in the eastern, central and southeastern parts of the State. In these sections prospecting has of late been more active than in the older districts in the western part of the State.

THE Amador Dispatch says a number of creditors have commenced attachment suits against the Gover mine during the past week, and the miners are feeling somewhat dubious about their wages unless they file liens. It is understood, however, that all claims will be settled within a short time, and that work will proceed as heretofore, except on a larger scale. There

is an immense body of fair-grade ore in sight in that mine, but it will require a larger mill to make the property a heavy-paying enterprise.

THE Mercer M. & M. Co., operating the famous Mercer mine, Camp Floyd district, Utah, met in Salt Lake, reports the Record, and decided to overhaul and repair the present milling plant and increase the capacity to 200 tons of ore per day; and further, to put in new crushing machinery. The company will also build a tramway, to be operated by steam power, from the mill to their mines. A \$25,000 dividend was authorized to be paid next Friday.

THE gold coinage executed at the Philadelphia mint during the fiscal year was the largest in the history of the mint. The total was about \$30,000,000, against only \$11,840,202 for the calendar year 1892, and \$10,282,185 for 1891. The largest previous record was in 1861, when the gold coinage was \$67,588,150, and in 1881, when the amount was \$67,272,810. The large coinage of the present year has been due principally to the demand for gold from the Treasury. The export demand now has to be met in coin, for the act of 1890 authorizes the Secretary of the Treasury to impose a charge for gold bars.

TALKING of damage to mines in Colorado by the recent freshets, J. E. Marden, contracting freight agent of the Union Pacific, having walked all the distance from Central City to Golden, Col., said: "No one can conceive of the destruction in that part of the country. Every mine in Central City is flooded, and there is not a vestige of a placer mine left in Clear Creek. Between Central City and Forke Creek there are 28 washouts, averaging from 10 to 15 feet in width. Between Idaho Springs and Golden there are 36 washouts." The mining men in Central City estimate the loss to the county at \$500,000.

CIVILIZATION is rapidly advancing in the Yukon region, Alaska. Forty-Mile City is the largest camp and contains 98 buildings, including miners' cabins, two large stores, one music hall, five saloons, one billiard parlor, one tin shop, two blacksmith shops, two assay offices, a mission church and one shoemaker. Provisions of all descriptions and clothing are sold at very reasonable prices. Canadian rye, British Columbia rum and high-pressure brandy are selling at the reduced rates of four bits a glass, \$8 a bottle, or \$36 a gallon. This reduction is owing to the large quantities now in transit to Forty-Mile creek.

MA. JACKSON, the discoverer of the "Jackson process" which is making some present stir in Colorado, is about to establish a plant in Pueblo. Boiled down, his process is about as follows: The ore is pulverized to 50 or 65 mesh fine; then roasted until the volatile impurities are driven off and the ore becomes sweet. A mixture of ores is generally used so that one may act as a flux to another. After roasting, the ore is chloridized, cooled and placed in tanks, where the base metals are dissolved out with water, leaving the gold and silver chlorides, which are dissolved by a solution composed of hyposulphite of sodium and salt. The gold and silver are then precipitated by electricity. The precipitates are washed, dried, melted and run into bars ready for shipment. The claim is made that a saving of \$22 per ton can be effected.

THE following Washoe mining companies had cash on hand as follows June 1st: Alpha, \$10,432.60; Alta, \$2364.84; Andes, \$19,996.71; Belcher, \$22,206.64; Best & Belcher, \$6398.51; Bullion, \$8305.06; Caledonia, \$6709.31; Challenge, \$2135.32; Chollar, \$14,829.03; Con. Imperial, \$2613.93; Confidence, \$5013.50; Con. New York, \$1470.25; Con. Cal. & Va., \$63,503.13; Crown Point, \$19,483.46; Eschschuer, \$1902.92; East Sierra Nevada, \$638.32; Gould & Curry, \$7962.21; Hale & Norcross, \$10,573.37; Julia, \$717.25; Justice, \$1715.94; Kentuck, \$1141.37; Lady Washington, \$220.14; Mexican, \$5167.83; Ophir, \$1144.25; Overman, \$4257.85; Occidental, \$124.29; Potosi, \$13,836.93; Savage, \$10,295.62; Scorpion, \$2094.41; Seg. Belcher, \$1577.46; Sierra Nevada, \$12,656.93; Silver Hill, \$392.02; Union, \$5479.23; Utah, \$1816.53. The Bodie District mining companies report cash on hand on that date as follows: Bodie, \$14,060.83; Bulwer, \$19.78; Mono, \$4531.85; Standard, \$34,064.86; Syndicate, \$952.86. The following Tuscarora mines had an indebtedness on that date as follows: Belle Isle, \$1920.30; Commonwealth, \$25,000; Navajo, \$2078.93; North Belle Isle, \$2361.81; North Commonwealth, \$1695.64; Grand Prize, \$416.67. The Nevada Queen had \$1359.70 cash on hand.

Personal.

SECRETARY W. C. RALSTON has returned from a business trip to Nevada county.

LIAUT. GILLATTA of the Debris Commission has returned from a business trip to Sierra county.

A. C. KYLA will represent Sup't Prendergast on the Comstock during the latter's European visit.

JOHN LAWANOA, formerly of Nevada City, will be the new superintendent of the Imperial mine in the Kennedy district.

W. F. STAUNTON has been appointed superintendent of the Congress mine, near Tombstone. E. B. Gage is the general manager.

CHAS. DOOLAN, a well-known metallurgist and mill superintendent, has been appointed superintendent of the Brown Bear Mining Co., Trinity county.

L. L. MYERS, late superintendent of the Spring Valley Gold Co.'s works at Cherokee, has accepted the superintendency of the Bloomfield mine of North Bloomfield at a salary of \$500 per month.

H. W. FAIRBANKS and R. P. HESGAN of the State Mining Bureau left Lone Pine on May 26th to ascend Mt. Whitney, and the following day succeeded, it being the first time that the summit of the mountain was reached so early in the year. They report enduring some hardship in the snow. On the summit the cold was so intense they only remained a few minutes.

WM. WHITA, a miner, who, if alive, is 62 years old, worked at the New Rocky Bar mine in Grass Valley, and left there in 1884 for Victoria, British Columbia. He arrived at Victoria and was then going to Williams creek. Since that year nothing has been heard of him. When he left he had considerable money with him. Any one knowing of his whereabouts or knowing whether he is dead or alive will confer a favor by writing to Roger Shackleton, Grass Valley, California.

Mines and Mills of Northern California.

TO THE EDITOR:—It was Lamartine who said that "viewing the ocean sets thought free." A roam through the mines and mountains brings the same result, I see—hence this letter. A revival of thought from new scenes is refreshing, and sometimes when dotted off into printers' ink is information to others. It was dusk when we boarded the cars at Oakland pier, but all was bright, balmy and cheerful when we stepped from them next morning in Shasta county, 257 miles north of our starting point. There is no use of dwelling on the grandeur of a cloudless sky, green forests and flowering fruit trees. It is spring, and spring in California means beauty everywhere.

After satisfying the inner man at the Middle Creek hotel, we commenced our roamings by going to W. P. Miller & Co.'s quartz mill. This is a new 10-stamp steam mill, not yet completed. It is intended for a custom mill, and will work ore and slimes by a new plan of Mr. Miller's introducing. All relating to the new plan of manipulating, after crushing, not being in, we are unable to give a proper account of it, hence must pass it by. Mr. Miller is a skilled millman—one who has had a varied metallurgical experience. This mill is not over 50 feet from the California & Oregon railroad, and only about one-quarter of a mile from the Middle Creek station, and is well situated for a custom mill. We are now on the westerly bank of the Sacramento river, a crystal clear stream having an abundance of water, and which in the near future will become important for manufacturing and electrical purposes. About a quarter of a mile from Miller's mill, going north, are the mill and mines of the Eureka Tellurium Gold Mining Co., Peter Shearer superintendent. Here is a fine, new, 10-stamp steam mill, with silver plates and concentrators, all well arranged. There are several mines connected with this property, among them the celebrated tellurium mine, which some years ago became famous from its great output of telluride of gold. The several mines connected with this company are as yet having only surface development; even the "tellurium" has less than 150 feet of depth. The gold of these ores is not only exceedingly fine, but otherwise hard to save by general mill process. Mr. Shearer is an active, earnest worker, and has an abiding faith in the ultimate of this property. His plant is well equipped, but what is wanted is depth on the lodes. This scratching on the surface is lost time. About one-quarter of a mile above Middle Creek, which is simply a railroad station, post and telegraph office, and what is called a hotel, is Soroni's 10-stamp mill, having merely silver plates and blanket sluices, as gold-savers. This is a neat little mill, which runs only at intervals on good pay ore from a mine belonging to the mill company which is being opened by a long tunnel.

About three miles from Middle Creek is the town of Shasta, once so lively from the great abundance of gold which flowed into it, and mined from the surrounding gulches; also famous as once the home of Jim Keene, Alpheus Bull and other notables. Shasta is a very pleasant-looking mountain town, but as far as population goes, seems a deserted village; but, taking into consideration the many quartz ledges in its vicinity, with energy and capital, the future may be better than the present. Its population want to wake up to the fact that a shallow hole in the ground, on a quartz lode, doesn't make a mine worth thousands of dollars. We tarried here but a short time, and, under the leadership of an old-timer, made a short cut through the woods for the Sacramento river, which is some four miles to the east. In due time we were on the borders of the stream, here having a width of about 300 feet. Our trail led down to the mill of the Shasta Gold Extraction Co., where is also a "flag station," known as "Calumet Spur." The Shasta mill is for working by the cyanide process, and reduces the ore dry; has dry-working pulverizers, and numerous iron and wooden tanks for leaching, etc. It is a neatly constructed mill, and is fixed for operating by steam and water power. The mill has been idle for some time, more from the fact that ores could not be purchased in quantities to justify running, than anything else. It was put up solely as a custom mill.

Nearly opposite the Shasta mill, on the easterly bank of the Sacramento river, is the Calumet mill, built some years ago by Almarin B. Paul, as general manager of the Calumet Gold Mining Co. This locality we reached by crossing on a neat wire suspension bridge, which carries large water pipes and which conveys water for power. This pipe is the ending of a large water system of ditches, flumes and pipes, extending some seven miles back into the mountains. The outlay for this power alone was over \$75,000. The Calumet is the finest of all California mill sites—there is order and beauty all through. The mill and numerous buildings are all on a direct line, on an avenue lined with shade trees, all fruit bearing; these, with gardens of flowers in profusion, vegetables, vineyards, and trees of all kinds of fruits, nuts, etc., make it not only beautiful, but a

homelike, comfortable place. The mill proper has now 24 stamps, with a large arrastra mill attached, cyanide tanks, etc., and all water-power facilities for 100-horse power and over.

These works, together with a three-mile tram road, have recently been leased to the Original Quartz Hill Gold Mining Company, a Chicago incorporation, which has as its general manager Mr. M. Maryanski, a mining engineer of graduated and practical experience, not only in Europe and Mexico, but California. Mr. M. is a decidedly modern miner, being a man of scope in his ideas and endeavors, and a clear-headed calculator—more of an American in his mining spirit than foreigners generally are, in this country at least. To this mill ten more stamps are now being added, bringing the capacity up to 50 tons or more per day. The plant will be fully equipped with silver plates, concentrators and canvas platforms, etc. Connected with this work is a three-mile steel T-rail road, which goes direct to the mine of the company—Quartz Hill. The Original Quartz Hill mine is one of the wonders of quartz deposits. The croppings for 650 feet about show an average width of 43 feet. There are some 200,000 tons in sight and ready to go to work on, and all mineralized. Of course the eye is not as correct in estimating the value of ore as an assay, but when all the advantages here are considered—first, that you can mine for about 50 cents a ton (the company will use machine drills running by steam); second, the facilities for transporting ore for a trifle, and working out the gold by water power on a capacity of 50 tons or more a day—why it looks as though California brickbats would pay, let alone so large a body of quartz that here and there shows specks of gold to the eye. The mine and railroad are under the supervision of Mr. De Yerski, a thoroughly educated mining engineer, and one who shows by his work that he is master of all he undertakes.

Being now in what is called "Old Diggins" mining district, our desire was to take in all possible and make Redding before dark. Our next move was to the mine of the Calumet Company. This mine has a large and lengthy outcrop, and has, above the adit level, furnished a large amount of ore. The mine is closed down for the present, as hoisting works have to be erected before working deeper. The next in line is the Union Consolidated or Walkers mine—Walkers of Salt Lake. Here development work is being carried on by tunneling, which at best gives but a meager depth on the lode. This lode taking in the Calumet is traceable by the croppings for over a mile and varies in width from 2 feet to 12 and 14 feet. The Walkers have a modern ten-stamp mill on the river, which at this time was not running. Mr. Rippetto, formerly of Salt Lake, manages this property. Next going north on the line is the "Old Spanish," owned by Hendy and others of San Francisco. Nothing is being done here, although there is a large outcrop of quartz to luvite enterprise and cash. Following still on is the "Central," belonging to Bless & Co. of New York. Here a good deal of work has been done, and at one time the market produced largely of rich ore, but latterly they have lost the pay chute, which always takes pluck and coin to recover. There is a good steam mill, with Huntington pans, concentrators, etc., connected with this property. Next claim is the Mammoth, belonging to a Philadelphia company. Here they are running a long tunnel, which will tap the lode pretty well down. The Mammoth is a very large deposit of quartz, averaging over seven feet in width. Mr. S. W. Cheney is in charge here. Next and last on the line is Hart's, but not the least by considerable. This mine is also known as the Texas and Georgia, and is owned by R. G. Hart, Sr. It is the best developed property on the line, having some five tunnels, which give a developed depth of about 900 feet below the apex. A very large amount of very rich ore has been extracted from this mine. Recently a fifth tunnel, 1700 feet in length, has reached the lode, developing another rich deposit of mineral. The width of this lode varies from 2 feet to 14. Mr. Hart, Sr., gives his personal attention to the management of his mine and mill, and that means a good deal, as Mr. Hart is a thorough miner, having been in the business from a boy. Connected with this property is a 20-stamp steam mill. The ore is transferred from mine to mill by a wire tramway, which works to completeness. This tram is about a mile long. The mill is equipped with silver plates, eight Improved Triumph concentrators, and canvas platform concentrator. The work of extracting the metal is about as complete as can be found in any mill working gold ores, and yet Mr. Hart does not claim he gets it all. This mill, like all the others in the district, is down by the Sacramento river, which furnishes a never-failing supply of good clear water. Taking a review of all the camps this day visited, I am impressed to say there is no locality in the whole State where is centered owners having so much wealth at their backs as in this Old Diggins district, and yet the one the least able

has done the most development and received the largest reward for it. Development makes the mine, and often the millions. Thus ends a very interesting and instructive day. We have not in this letter gone into details, and yet give a varied outline of a live and prosperous mining section of northern California. CARROL G. SPRAGUE.
May 30th, 1894.

Loss of Gold in Milling Ore.

TO THE EDITOR:—In your issue of June 2d, in an article under the heading of "Loss of Gold in Milling Ore," by T. A. Rickard of Denver, Colorado, the following occurs: "At any large, well-managed mill supplied with the output of any particular mine, it is found that about as much gold is obtained in the mill as the fire assay shows." Also, "Now, the mill gold is about 760 to 780 fine, therefore the saving by amalgamation is close to 76 to 78 per cent." These are very extraordinary statements, as they stand, without explanation.

The determining of per cent of gold saved by fineness of the bullion produced is a new idea to me, and I would like to get the figures, philosophy or chemistry by which in so simple a manner the percentage can be determined, as it has generally cost me a good deal of labor and time to accomplish this important point. By asking the question, How? I may be showing a lack of knowledge had by some younger students in milling, but let it be as it may, I don't consider myself too old to learn, though I may think such observations absurd. ALMARIN B. PAUL.

Room 5, Crocker Building, S. F., June 5, 1894.

Additional Information Requested.

TO THE EDITOR:—The writer is pleased to perceive, as pointed out by Mr. Rickard, that the Colorado milling practice is not in as bad a way as generally reported.

Mr. Rickard informs us that "as much gold is obtained in (Gilpin county) mills as the fire assay shows"—a very extraordinary good showing. He continues: "Now, the mill gold is about 760 to 780 fine; therefore, the saving by amalgamation is close to 76 to 78 per cent."

I fail to see the connection between the fineness of 760-780 of the mill gold with an extraction of 76-80 per cent by amalgamation. Will Mr. Rickard please throw additional light on the subject? G. F. DEETKEN.

Auburn, June 4, 1894

It Paid 281 Dividends.

Friday afternoon, says the Grass Valley Telegraph, the Idaho Gold Mining Company declared dividend No. 281, and the amount was \$6.53 per share, upon the capital stock aggregating \$20,257.58.

The glorious old company was dissolved Friday, the Court declaring it fully so. All debts have been paid and everything settled fully and completely and to the satisfaction of everybody.

During the working of the mine under the direction of the Coleman Bros., \$11,637,894 has been extracted from the lode, and out of that amount \$5,146,107.58 have been paid to the shareholders in dividends.

The mine has been so thoroughly written up during these years that it would be superfluous to repeat the old, old story. It has become famous throughout the world. The mine still goes on, only under another name—the Maryland—and Samuel P. Dorsey is the superintendent and principal owner. There were eighteen stockholders in the Idaho Company, as follows:

	No. Shares.
John C. and Edward Coleman	1,850
M. P. O'Connor	550
Geo. D. McLean	222
John Polglais	100
Chas. Webb Howard	70
John Carter	50
S. P. Dorsey (Trustee)	40
John Bree	30
Eugene C. Creller	30
Jos. Polglais	20
Frank G. Beatty	20
Wm. Coleman	20
Stella Dunston	12½
W. H. Miners	12½
Sarah A. Coleman	10
Jas. Tremewen	15
F. D. Sheener	10
Geo. W. Hill	10

A Special Prize.

W. F. Derham of this city, who won the first prize in the single-hand drilling contest at the Midwinter Fair, to-day received from San Francisco a special prize which consists of a handsome black walnut box containing a silver-plated hammer and drill, both regulation size. On the lid of the box is a silver-plated shield bearing the inscription that it was given to Mr. Derham as a special prize by the Dunham, Carrigan & Hayden Company. The recipient is very proud of the prize.—Nevada City Transcript, May 31.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894 by Henry G. Hanks, F. G. S.

Strabo (Book 16, chap. II, sec. 42): "The Lake Sirbonis (the Dead sea) is of great extent. * * * It abounds with asphaltum which rises, not, however, at any regular season, in bubbles like boiling water, from the middle of the deepest part; the surface is convex and presents the appearance of a billock. Together with the asphaltus there ascends a great quantity of sooty vapor, not perceptible to the eye, which tarnishes copper, silver and everything bright, even gold. The neighboring people know by the tarnishing of their vessels that the asphaltus is beginning to rise and they prepare to collect it by means of rafts composed of reeds. * * * The asphaltus is a clod of earth liquefied by heat; the air forces it to the surface, where it spreads itself. It is again changed into a firm and solid mass by cold water, such as the water of the lake; that it requires cutting or chopping for use. It floats on the water, which, as I have described, does not admit of diving or immersion, but lifts the person who goes into it. Those who go on rafts for the asphaltus, cut it in pieces and take away as much as they are able to carry. * * * It is natural for these phenomena to take place in the middle of the lake, because the source of the fire is in the center and the greater part of the asphaltus comes from thence. The bubbling, however, of the asphaltus is irregular because the motion of the fire, like that of any other vapor, has no order perceptible to observers. There are also phenomena of this kind in Apollonia in Epirus. * * * The Egyptians use the asphaltus for embalming the bodies of their dead."

Diodorus Siculus (Book 19, chap. VI) thus refers to the same subject; possibly this is his version of Strabo's account. These authors were nearly contemporaneous: "He (Demetrius) encamped near to the Lake Asphaltus, the nature of which it is not fit to pass over without giving some account of it. * * * Every year rises out of the middle of it great massy pieces of bitumen and pitch, sometimes bigger than three plethras and sometimes a little less than one, and upon that account the barbarous inhabitants call the larger pieces 'bulls' and the less 'calves.' These pieces of pitch and brimstone floating upon the water seem at a distance to be as so many islands. There are evident signs that forego and give notice of the casting up of this bituminous matter at least 20 days before, for a horrid smell of brimstone and pitch infects the air all round the lake at many furlongs distant, and all metals, whether gold, silver or copper, near the place change their natural color, which presently returns as soon as the brimstone is exhaled. The places bordering on it are so burning hot (by reason of the sulphur and brimstone under ground) and cast forth such an horrible stench that the inhabitants are very unhealthy and short lived. * * * The inhabitants on both sides of the lake are so earnest to carry away this brimstone that they fight one with another, and they bring it off in a strange manner without shipping, for they cast in huge buoies of bulrushes fastened together, upon which three or more of them place themselves, two of which ply the oars that are fastened to the bulrushes, and the third carries a bow and arrows to defend themselves against such as attempt to make up upon them from the other side, or that may offer them any violence. As soon as they come to the brimstone they get upon it and hew it to pieces with axes as pieces of stone out of a soft rock, and so loading the bulrush boat they row back. * * * And this profit and advantage the barbarians reap from it—they transport this pitch into Egypt and there sell it for the use of embalming the dead, for if they do not mix this with aromatic spices, the bodies cannot be preserved from putrefaction."

Thomas Shaw (Travels or Observations Relating to Several Parts of Barbary and the Levant, Oxford 1738, fol. 374) thus describes, second hand, the bitumen which rises on the surface of the Dead sea:

"I was informed that the bitumen for which this lake has been always remarkable, is raised at certain times from the bottom in large hemispheres, which as soon as they touch the surface, and so are acted on by the external air, burst at once with a great smoke and noise like the *Pulvis fulminans* of the chemists and disperse themselves round about in a thousand places. But this happens only near the shore, for in greater depths the eruptions are supposed to discover themselves in such columns of smoke as are now and then observed to arise from the lake, and perhaps to such eruptions as these we may attribute that variety of pits and hollows which are found in the neighborhood of the lake and compared very justly by Mr. Maundrell to

those places in England where there have been formerly lime kilns. The bitumen, in all probability, is accompanied from the bottom with sulphur, inasmuch as both of them are found promiscuously on the wash of the shore. The latter is exactly the same with common native sulphur, the former is friable, heavier than water, yielding upon friction, or by being set on fire, a foetid smell. Neither doth it appear to be as Dioscorides describeth his asphaltus of a purplish color, but is as black as jet and exactly of the same shining appearance."

"That dede See departethe the Lond of Ynde and of Arabye: and that See lastethe from Soara unto Arabye. The Watre of that See is fulle bytter and Salt: and zif the Erthe were made moyst and weet with that Watre, it wolde nevere bere Fruyt. And the Erthe and the Lond changeth often his colour. And it casterh out of the Watre a thing that men clepen Asfalt: also gret peces, as the gretnesse of an Hors, every day, and on alle sydes." (The Voiage and Travaile of Sir John Maundevile, Kt. (about 1370), chap. IX).

Professor Edward Hitchcock contributed a paper to the Association of American Geologists and Naturalists (Reports of the 1st, 2d and 3d meetings, Boston, 1843) entitled "Notes on the Geology of Several Parts of Western Asia," in which he quotes (folio 371) from the work of Robinson & Smith (Biblical Researches in Palestine, a journal of travels in 1838, Boston) who visited the locality, that there were then no bituminous springs or outflows of bitumen known, although there was a tradition among the Arabs to the effect that bitumen exudes from the rocks on the Eastern shore. After earthquakes, which are not uncommon, large masses of asphaltum are found floating on the surface of the Dead sea. After a violent disturbance in 1834, large quantities drifted to the south shore, of which the Arabs brought 6000 pounds to market. In 1837, after another earthquake, a mass like an island rose to the surface, of which the inhabitants sold \$3000 worth. This modern account quite agrees with the ancient statement of Diodorus Siculus quoted above.

Lieut. Lynch, U. S. army, was sent by the United States Government in 1847 to make explorations of the Dead sea. He frequently mentions asphaltum, once in the following words: "Most of the asphaltum met with in commerce is obtained from this lake and is hence called 'Jewish bitumen.'" In another place he ascribes the name "Lacus Asphaltites" to the quantity of asphaltum in a soft or liquid state (maltha) that floats on its surface and the bituminous inflammable stones found on its shores. "Modern travelers think the supply is either exhausted or that the accounts of the ancients were exaggerated. Large deposits have been overlooked by recent visitors or they do not exist." Lieut. Lynch found bitumen along the shores in occasional lumps and incrustations. The mineral was bright and smooth; when broken it looked like consolidated fluid. The Arabs called it 'Moses' stone.' (Fol. 304)

Tristram, quoted in the Encyclopedia Britannica, describes a valley in which were seen masses of bitumen, mingled with gravel and sulphur, unlike that picked up on the shores, which he thought might have been poured down in a shower. Lynch mentions at many localities on the shores of the lake a distinct odor of sulphuretted hydrogen, which accounts for the sulphur in a natural way.

Herodotus (Eratosthenes 119) thus describes a territory, "the name of which is Arderica: It is 210 stades distant from Susa and 40 from the well that produces three different substances, for asphalt, salt and oil are drawn from it in the following manner: It is pumped up by means of a swipe, and, instead of a bucket, half of a wine skin is attached to it. Having dipped down with this, a man draws it up and then pours out the contents into a receiver, and, being poured from this into another, it assumes three different forms. The asphalt and the salt immediately become solid, but the oil they collect, and the Persians call it 'rhadinace.' It is black and emits a strong odor."

Strabo (Book 17, chap. III, sec. 11) thus refers to asphaltum in Mauretania, now Algeria: "Somewhere there are also copper mines and a spring of asphaltos."

It is doubtful if the ancients were generally aware of the combustible nature of coal. Wood being plenty they did not require it, even if they had some idea of its properties. They were familiar with amber and the diamond but had no conception of their chemical composition.

Theophrastus, who died about 286 B. C., wrote in his "History of Stones" as follows: "XXVI—Certain stones there are about Tetras in Sicily, which is over against Lipara, which empty themselves in the same manner in the fire. XXVII—And on the promontory called Erineas there is a great quantity of stone like that found about Bena, which when burnt emits a bituminous smell and leaves a matter resembling calcined earth. XXVIII—Those fossil substances which are called coals, and are broken for use, are earthy. They kindle, however, and

burn like wood coals. They are found in Liguria, where there also is amber, and in Elis, in the way to Olympias over the mountains. These are used by the smiths. XXIX—There is also found in the mine of Scaptisylæ a stone in its external appearance somewhat resembling rotten wood, on which if oil is poured it burns; but when the oil burns away the burning of the stone ceases, as if it were in itself not liable to such accidents. * * * XXIII—Some of the more brittle stones there also are, which become as it were burning coals when put into a fire, and continue so for a long time. Of this kind are those about Bena, found in mines and washed down by torrents, for they will take fire on throwing burning coals on them, and continue burning so long as any one blows them. Afterwards they will deaden and may after that be made to burn again. They are therefore of long continuance, but their smell is troublesome and disagreeable."

Jet was called by the ancients black amber—*succinum nigrum*. When Roman traders told of the burning of amber for fuel by the natives of the shores of the Black sea, it is now supposed that the material was a variety of lignite, and not amber as reported.

Mineral coal was probably used in China long before it was known to the Western world. The travels of Marco Polo were written and circulated in manuscript form in 1298. The following is a translation of that part which relates to the use of coal: (Book 2, chap. XXIII).

"Throughout this province—Cathay—there is found a sort of black stone which they dig out of the mountains, where it runs in veins. When lighted it burns like charcoal and retains the heat much better than wood, inasmuch that it may be preserved through the night and in the morning still be found burning. These stones do not flame, except a little when first lighted, but during their ignition give out a considerable heat. It is true there is no scarcity of wood in the country, but the multitude of inhabitants is so immense and their stoves and baths which they are continually heating so numerous, that the quantity could not supply the demand, for there is no person who does not frequent the warm bath at least three times in the week and daily during the winter, if it is within his power. Every man of rank or wealth has one in his house for his own use, and the stock of wood must soon prove inadequate to such consumption, whereas these stones may be had in the greatest abundance and at a cheap rate."

Du Halde confirms this statement as follows: "The mines of coal are very numerous—perhaps no kingdom in the world contains more. They make use of this fuel on all occasions, which is of infinite advantage in so cold a country, and where wood for firing is very scarce." (General history of China, vol. I, fol. 22.)

The ancient Britons made use of coal to a certain extent. Stone bammers have been found in coal croppings, and the name (formerly "cole") is of British origin. After the conquest the Romans began to use it, for coal clinders have been found in Roman walls, and Roman coins in beds of cinders. Ireland was probably colonized by a civilized people at a remote period, as evinced by the prehistoric round towers and other remains.

Rev. William Hamilton (Letters Concerning the Northern Coast of Antrim, etc.; Dublin, 1786) makes the following statement: "In my last letter I mentioned some reasons which might induce one to think that these collieries (Ballycastle Bay) were wrought at a very remote period of time. But an accidental discovery has lately put that matter beyond doubt and has laid open a very curious circumstance in the history of the country." The author then proceeds to relate that "Some workmen driving an adit level in new ground, broke through the rocky sides into a cavern. As the opening was not large, two young lads were induced to enter with candles, who found an extensive labyrinth of galleries and passages in which they became lost. The coal miners, becoming alarmed, enlarged the opening and went in to find the boys, which they did after a whole night's imprisonment. Pillars were found supporting the roof; in short, it was found to be an extensive mine wrought by a set of people at least as expert in the business as the present generation. Some remains of the tools and even baskets used in the works were discovered, but in such a state that on being touched they immediately fell to a powder. There was not the most remote tradition concerning these ancient works, the age of which might be inferred from the fact that stalactites in pillars reached from the roof to the floor. The supports of the roof were covered with sparry incrustations, which the present workmen do not observe to be deposited in any definite period of time."

(To be continued)

ALUMINUM is now to be used for engraving in place of stone and steel. It is claimed that, besides the advantage of lightness, an aluminum plate will furnish 8000 impressions, against 80 to 100 from a steel one.

Kinks in the Cable.

Like all mundane things, the street-railway cable is liable to go wrong, get out of fix, bend, break or "frazzle out." All day long and far into the night this long, black, flexible rope goes gliding noiselessly and swiftly through its conduit like a great blacksnake, while the busy hum of traffic, the rattle of wagons, the hurrying feet of pedestrians, the rumbling cars themselves, keep up their din above it. Strong steel clamps attached to heavy cars, laden with tons of humanity at times, clutch it in their steely grasp, but without a moment's pause or slack it glides along as swiftly and as easily to all seeming as before, dragging the car and its load of humanity flying after it.

But sometimes, says the *Baltimore American*, this slender, though powerful reptile, or, speaking more prosaically the cable, meets with mishaps, and, one part disabled, the whole becomes helpless. There are three accidents that the car companies have to fear with regard to the cable, or what they universally call the "rope." They are breaking ropes, breaking a strand of the wire and a "kink," or a short bend in the rope. Of course, a clear break renders the rope instantly useless. If only a strand is broken it can generally be temporarily repaired in a few minutes, leaving the permanent repairs to be done after the rope stops for the night. A "kink" is a particularly aggravating mishap, and if bad requires a long stop; if only slight, remains a nuisance. The universal remedy in any of the cases is "splicing," unless it be for a very slight "kink."

To understand how the injuries to a rope are made and how repaired, it is necessary to understand what it is composed of.

The inside of a street-railway cable—the core, or, in railway parlance, the "heart"—is a closely woven, strong hempen rope. About this core is woven steel wires into strands which entirely cover and envelop the hempen rope. No method has yet been invented of connecting two ends of a cable except by the old method of splicing, and nobody has yet made any sort of machine to facilitate the work, which must all be done by hand. Probably the difficulty that would first suggest itself to the uninitiated would be this: If the wires are woven into each other, the diameter at that point will necessarily be a good deal larger than other parts of the cable, and that bulging would catch in the grips of the cars and play havoc. To obviate that difficulty the hemp core is removed from the spliced part altogether, which matters little, because it is put in, not for the strength it gives, but to make the cable sufficiently flexible. Therefore, when a splice is made the wires are unwoven for three feet back from either end and the hemp heart removed. Then those loose wires, three feet of them at either end, are twisted and woven into each other until the spliced part is three feet of solid wire of exactly the same diameter as the remainder of the cable.

Eight, ten, sometimes twelve men work together splicing a cable. They are always experienced men, with nimble fingers, and quick because loss of time means loss of money, and time is literally money; but fast as the splicers are and nimble as their fingers are, they will do well if the splice is completed in an hour.

The first splice, when the cable is put in, is done, of course, in the power-house, where everything is as convenient as it can be made. But sometimes the rope does not break in the power-house, but on the road. Sometimes it breaks short off, or a strand breaks and rips the cable for a block, possibly.

All sorts of mishaps may occur to it, so that it must be stopped and mended right in the street. This is a mean job. First, should the cable break in two, the immense tension which is always on it jerks the broken ends a whole block or more away from each other. Plenty of slack rope must be furnished at the power-house, a number of horses must be harnessed to either of the broken ends, and they must be pulled together, and then plenty of "slack" to work with pulled out of a manhole. The splicers hurry to the spot with their tools and work at a disadvantage. If only a strand or two is broken the task is easier. In that case, the ruptured place nearly always gets into the power-house before it is so bad as to stop the cars.

In order that a broken strand should never pass in and out of the power-house before being repaired, an electric detector has been invented, so that the fact of a broken strand or even wire is communicated to the engineer as soon as it enters the power-house and before it can get out again. The detector is a very simple contrivance, being merely a piece of iron with two prongs, between which the cable has just room to pass. The cause of these various mishaps is almost invariably the mismanagement of the grip by the gripman. Of course not every splice is due to this, because every new rope that is put in must be spliced.

In this connection, it is interesting to know how a new cable is put in in place of an old one, for they must be

changed now and then. The old cable is cut and the new spliced roughly in the end that is leaving the power-house. Then the other end is started on a large coil, and as the new cable is unwound from one coil the old cable is wound on another until the new one comes around. This is decidedly easier than pulling the cable around with horses. When a new cable is started, the first thing is to get as much tar in it as possible. It is snaked in tar; tar is poured over it by the hour as it runs, etc., until it gets saturated with tar from surface to the center of the heart and the outside wires cannot be seen, the whole looking like a solid stick of licorice.

Arcturus, the Greatest of all Suns.

Since Sirius has practically disappeared with the progress of the year, the brightest fixed star in sight is Arcturus. It is worth while for anybody to take the very slight trouble needed to find Arcturus, for who would not wish to see what is, perhaps, the greatest sun contained in the visible universe? I suppose, says G. P. Serviss, in the *N. Y. Sun*, everybody knows the figure of the "Dipper" in the sky. At this season, about 9 P. M., it is nearly overhead in the north, its handle being to the east and its upturned bowl to the west of the meridian. Follow the curve of the handle to the end and extend it with a similar curvature for a distance somewhat exceeding the entire length of the Dipper, and you will find Arcturus. There is not the slightest danger of missing or mistaking it, for there is no star in that part of the sky possessing one-quarter of the brightness of Arcturus. A soft reddish tinge distinguishes its light from that of all its fainter neighbors. This reddish hue, which I believe to be variable, has a peculiar significance, as we shall see.

The statement will be found in some of the old school-books that Arcturus is probably one of the nearest of the stars. As a matter of fact, it is one of the most remote of those whose distance is measurable. It must be admitted that the few measures that have been made are very discordant, and in what follows I shall assume the correctness of the results obtained by Dr. Elkin. The measurement of the distance of a star is a very beautiful problem, and the fundamental principle is perfectly simple. It depends on the revolution of the earth around the sun. On the 1st of January the earth is about 186,000,000 miles from the place it will occupy on the 1st of July, because on those two dates it is at opposite points in its orbit, and the distance across the orbit is 186,000,000 miles. The diameter of the earth's orbit thus serves the purpose of a surveyor's base line. It is plain that the direction in which a star is seen cannot be exactly the same from both ends of that line unless the star's distance is so immense that the diameter of the earth's orbit bears no measurable ratio to it. Most of the stars are so distant that that ratio cannot be ascertained, but there are a few whose apparent places are appreciably different when viewed from the extremities of our 186,000,000-mile base line. According to Dr. Elkin, the position of Arcturus is thus shifted to the amount of 0.018 of a second of arc, and this is called its parallax. How exceedingly delicate the methods employed in measuring such a quantity must be can, perhaps, be understood when it is stated that 0.018 of a second of arc is equal to the apparent distance between the heads of two pins placed one inch apart and viewed from a distance of 180 miles!

Having ascertained the parallax of a star, the next step is an easy one. Multiply the earth's distance from the sun, 93,000,000 miles, by the number 206,265, which is a mathematical constant that I shall not here undertake to explain, and divide the result by the parallax of the star. The quotient will be the star's distance in miles. If we apply this rule in the case of Arcturus, we have

$$\frac{19,182,645,000,000}{0.018} = 1,065,790,250,000,000 \text{ miles.}$$

In round numbers, one thousand millions of millions of miles, or about 11,400,000 times the distance of the sun from the earth. The reader may jot down in his notebook the number 19,000,000,000,000, leaving off the less significant figures we have used above, and it will always enable him to ascertain the approximate distance in miles of a star whose parallax is given, this number being used as a dividend, and the parallax, expressed in the form of a decimal fraction, as a divisor.

Now, having found what Arcturus' distance is, another simple calculation will enable us to compare the actual amount of its light with that of the sun; in other words, to say how much greater a sun than ours it is.

Various estimates have been made from time to time of the light which we receive from certain of the brightest stars compared with that received from the sun. It is probably fairly accurate to say that the sun sends us about 25,000,000,000 times as much light as Arcturus does; in other words, that it would take twenty-five thousand million stars as bright as Arcturus to make daylight on the earth.

But, as everybody knows, the intensity of light decreases

with increase of distance. If we were twice as far away from the sun as we are, we should get only one-quarter as much light from it as we do; if we were three times as far away, we should get only one-ninth as much light, the light varying inversely as the square of the distance. Situated where we are, the sun gives us enormously more light than Arcturus does; but we have just seen how enormously farther than the sun Arcturus is. Let us suppose, then, that the earth could be removed to a point half-way between the sun and Arcturus. In that case those two shining bodies would be on equal terms so far as distance was concerned. Which, then, would give the greater light to the earth? Arcturus, unquestionably. The real distance of Arcturus is 11,400,000 times the real distance of the sun; but at a point half-way between them the sun's distance would be 5,700,000 times greater than it now is, while Arcturus' distance would be diminished one-half. But since light varies inversely as the square of the distance increases, the sun's light would be diminished the square of 5,700,000, or 32,490,000,000,000, while that of Arcturus would be quadrupled. Now, glancing back, we see that in the present position of the earth the sun's light exceeds Arcturus' light in the ratio of 25,000,000,000 to 1; but with the earth half-way between them, the sun's light has diminished, as a result of increased distance, 32,490,000,000,000 times, and Arcturus' light has increased, through decrease of distance, four times. Multiplying together these two numbers, and dividing the product by 25,000,000,000, we get 5198, which is the number of times that the light of Arcturus exceeds the sun's at an equal distance; so that Arcturus is really, as far as radiating power goes, equal to 5198 such suns as ours!

Does the heat of Arcturus exceed that of the sun in the same ratio? Very likely it does. If, then, we were as near to that giant star as we are to the sun, we should be not only blinded, but burned up. The frame of the earth itself would melt and dissolve and burst into a cloud of fiery vapors. If we suppose that the intensity of the radiation of Arcturus is the same as that of the sun per unit of surface, Arcturus must be about 72 times as great in diameter as the sun, and about 375,000 times as large in volume. Its diameter in miles is, on that supposition, no less than 62,350,000! Imagine all the planets of our solar system removed to Arcturus and set revolving around that star in orbits of the same size as those in which they travel around the sun. Poor little Mercury, when in perihelion, would be plunged more than 2,500,000 miles beneath the blazing surface of that marvelous sun; neither Venus nor the earth nor Mars, nor Jupiter would be able to withstand its overwhelming heat. Even Saturn, at a mean distance of 855,000,000 miles from the surface, would also be overwhelmed with that mighty outpouring of radiant energy; Uranus, 1,750,000,000 miles away, would be a most torrid and unendurable place of abode, if, indeed, it would be habitable at all, and Neptune, a thousand million miles more distant still, would broil under a fervid temperature nearly six times as intense as the mean temperature that the sun now imparts to the earth. If Arcturus is surrounded by inhabited worlds, it is plain that they must keep a very respectful distance between themselves and their solar ruler, or else they are inhabited by beings whose blood would freeze in their veins during a midsummer day in the Desert of Sahara.

We have some knowledge also of the kind of sun that Arcturus is. It belongs to a separate family from that of our orb of day. Leaving out of account their difference of magnitude, they are as unlike as an elm and an apple tree. I have spoken of the red tinge visible in the rays of Arcturus; the analysis of its light indicates that it is surrounded by a vast mantle of metallic vapors, enormously deeper and more extensive than the similar surroundings of the sun, shutting out an immense quantity of light, while at the same time the surface of the huge globe within glows with a greater intensity of heat than prevails on the sun. There is some reason for thinking that the screen may eventually be stripped from the face of this wonderful star, and that, as Sirius has done, it may change from red to white. Such a change might imply a tremendous increase of radiation. In 1852 its light suddenly faded, and the dazzling whiteness of its rays astonished those who had observed the change. In a few years it became red again. Its color is paler now than it has been in past years. This spring it has sometimes appeared to me to have almost parted with its familiar ruddy yellow tinge. What do such mutations import?

It would surely be worth the risk involved if we could place ourselves within easy observing distance of Arcturus, and study the play of solar energies there on a scale which dwarfs even the gigantic phenomena of the sun. And possibly the improvements that the coming century will undoubtedly bring to the telescope, the spectroscopic and other instruments of research will enable us to approach Arcturus in effect, if we cannot in fact; for man already sits like a god upon his little earth, and reaches out to the orbs that surround him.

SIPHON—RIVER SANTA CATALINAS IN DISTANCE, SANTA CRUZ VALLEY.

SIPHON AFTER CROSSING RIVER, SANTA CRUZ VALLEY.

An Arizona Enterprise.

Some one has figured out that the area of land cultivated by irrigation is greatly in excess of that cultivated by means of natural rainfall. In India 25,000,000 acres are made fruitful by irrigation. In Egypt there are about 6,000,000

acres, and in Europe about 5,000,000. The United States has about 4,000,000 acres of irrigated lands, and vastly more that is irrigable. This irrigated area is constantly increasing in our country, nowhere more rapidly than in Arizona.

The subject of irrigation is, indirectly at least, of sufficient consequence to mining enterprises to merit notice. Wherever mining is going on, abundant water and supplies are requisite, and, in this regard, anything that tends to produce abundance is of importance.

The accompanying illustrations, reproduced through the courtesy of the *American Mail and Export Journal*, are of

the workings of the Rillito Canal Company, the first of its kind in Arizona. The company originally began with a ditch on the Fort Lowell reservation, commencing about three miles east of its western boundary, finally developing it into a system for carrying water across the Rillito river to a fertile mesa of several thousand acres south of the

river and near Tucson. To do this they had to take the water of the canal from one bank of the Rillito river to the other. They did it by using an inverted siphon of California redwood, beveled, banded, and buried under the river bed, at right angles with the channel. It is 450 feet long; four feet five inches in diameter. It is built in a hydraulic grade of one in 514, and at the lowest point of curvature it has a gate valve and pipe for flushing, in case of sediment or sand getting in. At the eastern end is a large forbay entering the siphon, provided with a suitable sand-box and gate opening into a spillway cut diagonally to the river and emptying into it at a lower level.

H. W. Fassig of Columbus, Ohio, is the secretary of the corporation.

The company is deservedly making a success of the enterprise, and if any one deserves credit for making two blades of grass grow where but one grew before, an enterprise is then worthy of commendation that makes a fertile field of what was a sterile desert, thus contributing to the comfort and convenience of the miners of Arizona.

THE average number of working days in various countries, according to the *London Engineer*, is as follows: In Russia, 267; in England, 278; in Spain, 290; in Austria, 295; in Italy, 298; in Bavaria and Belgium, 300; in Saxony and France, 302; in Denmark, Norway and Switzerland, 303; in Prussia, 305; in Holland and North America, 308; and in Hungary, 312.

A NEW UNIVERSAL CLOCK consists of a terrestrial globe which revolves once daily over a base divided into 24 hours—12 white and 12 black. The time for any part of the world can be seen at a glance without calculation.

UP IN Maine they are trying the milk cure for the habit of using intoxicants. The patient drinks milk till he is too full to hold any other liquid. The scheme works finely.

Sinking Through Water-Bearing Strata.

M. Gobert has devised an improved method of sinking shafts through water-bearing strata. In the original invention of M. Poetsch, by which most of the difficulty of working in wet "measures" was overcome, the soft material to be excavated was frozen by driving into it pipes through which a freezing liquid was circulated. The temperature of the liquid was reduced by passing it through cooling coils on the surface. The drawback to this method, however, was that the freezing liquid in the tubes was at a pressure above that of the atmosphere, and there was thus a tendency for it to leak out at every weak spot in the tube system. Such leaking prevented the congealing of the adjoining material. M. Gobert's efforts have been directed to securing a system in which the pressure within the freezing tubes would be lower than that outside, and he has succeeded in doing this by the employment of anhydrous ammonia, which is used directly in the tubes instead of the secondary freezing liquid used by Poetsch. The ammonia gas is compressed until it assumes a liquid state, as in the regular ammonia compression refrigerating machines, and is then injected into the freezing tube system, where it evaporates and abstracts heat from the surrounding material. The pressure of the ammonia gas is always lower than that of the outside. The tendency of the liquid, when injected into the freezing tubes, would naturally be to drop at once to the bottom and collect there. In such case the evaporation would be comparatively slow, and the freezing process correspondingly inefficient. To prevent this, the inner tube is made in the form of a worm. This worm is closed at its lower end, and punctured along its whole length with a number of minute holes, through which the liquid ammonia escapes in small quantities, and is rapidly vaporized. By suitably arranging these escaping devices the freezing action may be concentrated at any depth along the line of the tubes. By this system, whenever the strata at the bottom of a shaft is so soft, or so flooded by water that the workmen cannot make headway with their sinking, the pipes are run down, the freezing mixture is forced in, and the part to be excavated becomes so soft that the pick and the shovel become once more effective, and operations can be continued.

How to See Cataract in Your Own Eye.

The following simple method enables a patient to see a cataract in his own eye and note its growth and development, probably better than any oculist can observe it for him:

Cataract is said to be due to the gradual deposition of oxalate of lime in the substance of the crystalline lens, at first in small spots or streaks, sometimes in one part and sometimes in another. The deposit gradually increases until it penetrates the whole of the lens, causing blindness. The remedy, then, is to remove the lens, and after its removal the patient needs a substitute in the form of highly magnifying spectacles.

All that is necessary to enable a patient to see his own cataract for himself is a piece of card and a needle—a visiting card will do very well. Pierce a clean round hole near the middle of the card and hold the card up to the light close to the eye, looking preferably in the direction of a piece of blue sky. With the card near to the eye, the patient will not see the small hole pierced by the needle, but he will see a comparatively large faintly illuminated field with his cataract projected upon it. He is, in fact, observing the shadow cast by his cataract on the retina at the back of his eye. With

a small puncture in the card the shadow so thrown is comparatively sharp. But with a normal eye an evenly illuminated field or clean disk will be seen. The patient may thus map down his own cataract, and settle for himself whether it is extending or not. None of the oculists I have seen have known of the method, and there may, consequently, be some advantage in making it public.—J. S., in Knowledge.

Freezing Alcohol.

The success attending Professor Dewar's experiments in the freezing of absolute alcohol has a peculiar interest, in view of the fact that 200 degrees C. was the utmost limit of cold reached or obtained by man, viz: by the use of liquid oxygen. Professor Dewar allowed some liquid ethylene to flow through a brass tube surrounded by solid carbonic acid and ether, and when this cooled it was passed into a large test tube, with a flattened bulb at the end, the bulb being full of absolute alcohol.

The evaporation of the ethylene was then accelerated by the use of the air pump, and the alcohol was frozen into a mass as clear and transparent as crystal. The tube containing it was turned bottom upward, and as it melted it assumed the exact consistency of glycerine, flowing in a sluggish way down the sides of the tube. Ether requires less cold than alcohol to freeze it, and in several of Professor Dewar's experiments ether ice formed on the sides of the glass vessels. Besides this, the warm air of the theater was constantly condensing as snow or hoar frost on some of the vessels used in the experiments, and the chief difficulty of the occasion was the projecting of the experiments on the screen by the electric light, so that all present might see what was taking place.—Scientific American.

An Alloy of Gold and Aluminum.

During a series of experiments for the Royal Society's committee on researches upon alloys, Captain Hunt has made a discovery that will probably be utilized in the coinage of money. His alloy consists of 78 parts of gold to 22 of aluminum. These proportions, moreover, are the only ones in which these two metals alloy perfectly.

The product, it is said, is of a beautiful purple color, with ruby reflections, and cannot be imitated. Besides, as gold is 7.7 times heavier than aluminum, the same weight of the latter will be 7.7 times greater in bulk than the former.

Utilizing the Central Heat of the Earth.

In an address recently made before the Chambre Syndicale des Produits Chimiques in Paris, Mr. Berthelot proposes to utilize the central heat of the earth by sinking a shaft or shafts to a depth of 4000 meters. At the bottom of these shafts he believes that a temperature of 160° to 200° Cent. would be found and the pressure developed could be used for running machinery. M. Berthelot believes also that at this depth we would reach a source of thermo-electric energy almost without limit.

AN APPARATUS for "converting solar heat into continuous power" has been invented by Melvin Linwood Severy. Machines have been made already in which the sun's rays are reflected on to a small boiler, thus generating steam, but so far they have been mere laboratory toys which will not stand the practical test of steady work. If Mr. Severy's apparatus goes further than this, and proves to be a commercial success, its sphere of usefulness should be almost unlimited.—Chicago Journal of Commerce.

THE new cable from Nova Scotia to the Irish coast will be 2200 miles long. The work has already been started.

Diplomas awarded. To begin students need only to know how to read and write. Send for FREE Circular of Information, stating the subject you think of studying, to The Correspondence School of Mechanics and Industrial Sciences, Scranton, Pa.

4000 STUDENTS.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., Patent Agents,

TELEPHONE No. 658.

A. T. DEWEY. W. B. EWER. OEO. H. STRONG.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$6.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Mechanical Progress.

The New Army Rifle.

The first consignment of the new army gun, the Krag-Jorgensen rifle, goes from Springfield to the infantry corps at Fort Omaha. The new weapon weighs about eight pounds, including its knife-shaped bayonet. Its barrel is 30 inches in length; its magazine contains five cartridges. It can be used either as a single-shot rifle or as a repeater, and in the former case can be manipulated rapidly enough to discharge 30 shots a minute. One striking characteristic of the arm is its small caliber. The present Springfield rifle has a bore of .45 of an inch; the new rifle one of .30 of an inch only, just about large enough to admit an ordinary lead pencil, and enables the soldier to carry 175 or even 200 rounds of ammunition, instead of 100, as at present. The bullet is about an inch long, of hardened lead, coated with nickel. The charge of 37 grains of smokeless powder burns with little residuum, but smokeless is only a relative term. There is a smoke, or light, feathery vapor, but at a distance it is scarcely noticeable.

At a range of 200 yards it is said to have sent its tiny nickel-clad bullet through 45 inches of poplar planking. At 2000 yards, or considerably more than a mile, it pierced the body of a horse at the shoulders, and would have gone completely through three men. At 2800 yards it pierced four inches of planking, and at 3200 yards it still had force enough to go through a human body. But, while the new arm has developed this terrible power, it is true that at short ranges, at least, it lacks the accuracy of the old-style rifle, and there is some apprehension, too, that its intricate mechanism may not stand the test of hard service on the frontier.

Sweeping with Compressed Air.

One of the most notable of the present century's small inventions is an air pump for cleaning purposes. A hose pipe charged with air under 50 pounds pressure to the square inch is turned upon the article or room to be cleaned. It is used in precisely the same way as the water and the hose for washing purposes. It is far more effective in its result than brooms, beaters or brushes, as it searches out and penetrates every crevice and cleft in woodwork.

This device is at present applied to cleaning cars, but so perfect is its work that it is only a question of time when it will come into use for other purposes. Hotels and large buildings might be swept out and dusted in an incredibly short space of time. Carefully managed, this air pressure would rid the room of every particle of dust, clean furniture, carpets and the heavier articles of bric-a-brac and ornaments. It would do the work of a dozen people.

It is now in order for some home missionary to invent some simple device that will work an air pump and current for household use. Its introduction would revolutionize housekeeping and solve the heretofore hopeless problem of clean rooms, and will keep furniture covers and carpets. It would be economical, as it would render less service necessary and would save a large portion of the wear and tear of furnishing textiles. In houses where there is hydrant water it would not be at all difficult to attach an air pumping apparatus to the kitchen or bath-room faucet, and thus furnish power for every floor.

Some years ago it was said that there would never be an invention that could sweep the dust, but at the present rate of things the problem is practically solved by this simple and easily used device.

At a cost of \$12,500,000 Manchester, England, is just completing a system of water supply by which Thiermere, one of the English lakes in Cumberland county,

95 miles away, has been dammed and water supplied to the city of the best quality in quantities sufficient for all probable needs. The city of Mexico, at a cost of \$10,000,000, is just completing a drainage system that will carry the overflow of the great basin to the sea.

An Alloy Which Adheres to Glass.

M. F. Walter has found that an alloy consisting of 95 parts of tin and five parts of copper adheres so tenaciously to glass that it may be employed as a solder to join the ends of glass tubes. It is obtained by adding the copper to the tin previously melted, agitating with a wooden stirrer, casting or granulating and then remelting. It melts at about 360 degrees C. By adding from a half to one per cent of lead or zinc, the alloy may be rendered either softer or harder, or more or less easily fusible. It may also be used for silvering metals or metallic thread.—Revue Scientifique.

It appears by recent newspaper reports that the Adams-Blair "direct process" of steel making is again attracting attention. This process consists in reducing an iron ore by gas to form a metallic sponge, and using this sponge in the open hearth furnace for steel manufacture. We have no details of the Adams-Blair process as at present operated, and the amount of capital which has been sunk in fruitless and foolish schemes of this sort is not calculated to inspire confidence; but so good an authority as H. M. Howe, in his "Metallurgy of Steel," expresses the belief that the direct process may yet be able to compete with the blast furnace in furnishing material for the open hearth furnace; and the continued commercial success of the Carhon Iron Company, which uses the Eames direct process, and turns a very high grade of steel, seems to show that this belief is not without reasonable foundation.—Chicago Journal of Commerce.

EFFORTS innumerable have been made to overcome the smoke nuisance, and varying successes have been made. Messrs. Braid & Co., 113 Fore street, London, are introducing a very simple grate for the purpose. It really consists of two grates, the one at the top consisting of only two bars, whereas the one below is of the usual size. The bottom grate is filled with coal, while the top one is laid in the usual way, and a light then set to it. The heat works downward and ignites the coal below. There are, in a sense, two fires, the one above the other, which has the effect of causing a consumption of the smoke, so that only a small percentage escapes up the chimney. When the fire above is exhausted, that below working downward has the same effect, with the result that it is estimated that only about ten per cent of the fuel is left unconsumed.

COLONEL DONNETHONE has invented a new magazine gun, for which he claims the following advantages: Greater penetration, lower trajectory, increased storage capacity in magazine, quicker action, simpler construction, lighter and cheaper; and it must be admitted that the tests to which the weapon has been subjected were well sustained. An important feature of the gun is that the center of gravity is preserved whatever the condition of the magazine. As will be seen, the gun possesses advantages which are highly appreciated by soldier or sportsman.

TWO NEW locomotives have been made by the Winterthur Company for running express trains on the St. Gothard railway without changing the engines. One of the locomotives has three cylinders, the high-pressure in the middle, and on the level and easy gradients, it is stated, the steam from the high-pressure cylinder will exhaust into the two outside, while in heavy gradients all three cylinders will take their steam directly

from the boiler. The other engine has four cylinders, coupled two and two, so as to constitute four high-pressure cylinders on heavy gradients, or two compound engines when the traction is easy.

IN A new invention the mechanism is described as a hollow cylinder 10 1/4 feet in circumference, to which the grain of a piece of oak of the width of the cylinder has been transferred, this grain being covered with a soft cement which sinks into the depression, and in these about 200,000 bits of metal-like type are set, above this being placed a small, smooth steel cylinder adjustable to different heights; between the two cylinders, both revolving, a piece of birch, poplar, bass, spruce or maple may be passed which comes out with the grain of the oak transferred to it.

Metallurgy and Ores.

Electric Progress.

Fatalities Due to Electric Shocks.

After studying and classifying fatalities due to electric shocks, including the executions which have taken place in New York, MM. Biraud and Lacassagne of Lyons announce that electricity causes death in two ways—first, by producing mechanical lesions of the blood vessels and nervous system; second, by stopping the respiration and action of the heart. Deaths belonging to the former class are caused by lightning and static discharges from powerful batteries; but those of the second class are met with in shocks, from high-tension currents used industrially. A French paper, in commenting upon the investigation, takes up the subject at this point as follows:

"These two classes of deaths are distinguished also in practice by a most important fact. While disruptive discharges of the first class cause death absolutely, the electric action in the second case most frequently puts the victims in a state of apparent death, and they can be revived by resorting to artificial respiration immediately after the accident. Thus, in accordance with a principle stated by d'Arsonval, a person who had received an electric shock should be treated exactly as one who has been drowned. None of our skillful physicians have, it is said, succeeded in killing with certainty a luckless rabbit, even by employing a current of 2500 volts and 20 amperes. When the experimenter has believed he has succeeded, it has still artificial respiration. Yet it is questionable if the machines used for electrocution in America give 1500 volts. D'Arsonval some time ago challenged the American doctors to try artificial respiration on the patients immediately after electrocution."

Boiler Incrustation.

The frequency of troubles with steam boilers, especially those used on sea-going vessels, caused by incrustation and corrosion, has been a source of so much expense for making repairs, to say nothing of delays, that every process suggested to minimize the difficulties is given special attention. There have been compounds upon compounds used to prevent these decays, and some have been found to be good and some otherwise; and few, if any, have been tried that have not injured in some way the internal surfaces of the boiler. A novel method, called an enamelling process, has been the subject of careful investigation and practical experiment, and is reported to have given good results. The method consists in the coating of the interior surfaces with a deposit in the form of a smooth, black film or enamel, similar to an electro deposit, thick enough to protect the metal underneath from corrosion, and so thin that the boiler loses none of its steam-generating power. The application is simple, the process material being injected into the boiler through a cock of lubricator pattern at such times as desired, and the surface below the water level thus becomes coated with the enamel. The makers claim for the process that the enamel is impenetrable by acids, it protects the boiler from the corrosive agents contained in almost if not all waters, it prevents incrustation, and does not injure the boilers. It is also claimed to be inexpensive, is convenient of handling and effective in its purposes.

Effect of the Trolley on Watches.

A great many men are wondering what is the matter with their watches. Never since the town was a town have there been so many pocket timepieces taken in for repairs. The trouble lies in the trolley. The introduction of the electric wire for propulsion, making the car stop and go fast or slow, affects the average watch in a similar manner,

and fortunate is the man who gets off a trolley with his watch in the same condition that it was before. He may catch a train or reach bank in time to pay a bill, but it will be by town-clock time, not his own. Every watch thus affected has to be demagnetized. —Philadelphia Times.

Windmills for Generating Electricity.

An English engineering company is conducting, upon an extensive scale, the charging of electric storage batteries by the use of windmills. The motor consists of a set of five curved vanes (measuring 7x20 feet each) attached longitudinally to a vertical shaft. A shield is so arranged as to permit the wind to strike only such vanes as present their concave surfaces. This shield moves automatically into the proper position. The mill is of 20 feet horizontal diameter, and supported 30 feet in the air by a strong iron frame. Friction rollers operating in oil baths take care of all the working parts of the apparatus, including the side thrust produced by the wind pressure. This alleviation of friction allows the mill to actuate in a very light breeze. With say a seven or eight mile per hour wind velocity, two-horse power may be generated. In a certain English town a motor of this description operates a five-horse dynamo, being connected thereto by belt gearing. The dynamo mentioned is utilized in the charging of accumulators, the latter producing a current available for lighting or power purposes.

Ocean Cables.

A new 2200-mile cable is to be laid from Halifax, N. S., to England. This, with the two now in process of submergence, makes twelve cables between America and Europe. The original 1858 cable weighed 93 pounds per mile and had a conductor of seven copper wires of 22½ gauge. Price of deep-sea wire per mile, \$200; price of spun yarn and iron wire per mile, \$265; cost of outside coating of tar and gutta-percha, \$25 per mile; total cost per mile, \$485. At \$485 per mile the total cost of the 2500 miles of deep-sea wire was \$1,212,500. To this add 25 miles of "short-end" wire, costing \$1450 per mile, and we find that the first ocean cable, exclusive of instruments, cost \$1,250,000. Cables can now be made and laid for less than \$300 per mile.

DR. OCHSE'S new electrolytic cartridge for shot firing in mines is composed of an ampulla of very thick glass filled with slightly acidulated water, into which penetrate two small platinum electrodes connected with two copper wires. It is placed at the bottom of a mine, which is afterward rammed in the usual way. The water on passing the electric current is decomposed into oxygen and hydrogen, and these two gases form a detonating mixture which explodes, we understand, at about 400 or 500 degrees C. The cartridge is described by M. Chalon in a recent number of *Le Genie Civil*.

AS THE outcome of his many experiments on the phenomena of the electric arc, M. Violle thinks he has established the fact that the carbon in the arc is always in the state of ebullition. It is well known that the temperature of a substance in ebullition is always constant, and this therefore, would account for the constancy of temperature, and hence of brightness, in the arc.

A SPECIAL MOUTHPIECE for public telephones is being introduced in Germany, with the object of avoiding the spread of diseases carried by the condensed moisture of the breath. A pad or a large number of discs of paper, with a hole in the middle, is inserted in the mouthpiece, and the upper disc of paper is torn off after every conversation.

Practical Information.

Return of a Celestial Wanderer.

Halley's comet is coming back—the comet which in the year 1066 shed a celestial splendor over the Norman conquest and whose terror-inspiring visit was commemorated by the hand of Queen Matilda in the Bayeux Tapestry; the comet that in 1456, the year of the battle of Belgrade, scared Turk and Christian alike, and was anathematized by a bull from the Pope; the comet whose strange scimitar form still chilled the marrow of the ignorant and superstitious at its latest return in 1835. It is yet far away, says a writer in the *New York Sun*, but the eyes of science see it, already within the orbit of Neptune, rushing sunward and earthward with constantly increasing velocity as it falls along the steep curve of its orbit. And a call to arms, a call for preparation, has just been issued from one of the chief watch-towers of astronomy.

Halley's comet is not one of the insignificant crowd of little comets, so many of which are discovered by industrious stargazers every year, and which nobody outside of the observatory ever sees. On the contrary it furnishes, or at least has done so hitherto, a splendid spectacle in the sky. Of course in speaking of ordinary telescopic comets as insignificant I refer only to their apparent size and brilliancy; in a scientific sense they frequently possess the highest interest and significance. But Halley's comet is one that, when favorably situated, commands every eye, and does not need to be looked for. During at least eighteen centuries it has periodically astonished the inhabitants of the earth. In 1456 its tail was 60 degrees long. In 1835 it had a tail 20 degrees in length.

It was after its appearance in the time of Newton, in 1682, that the fact came to be recognized that this comet is a regular visitor to the neighborhood of the sun; in other words, that it travels in a long elliptical orbit. When nearest it is about 56,000,000 miles from the sun, and far inside the orbit of the earth; when most distant it is about 3,370,000,000 miles from the sun and beyond the known limits of the planetary system.

Now that astronomers have undertaken the prediction of the exact period of its return it will be interesting to see who will hit nearest to the mark. All those of us who actually see the great comet on its return will surely find it doubly interesting, because it is like a slowly revolving hand upon the dial of history. It passed across the sky twice twelve years before the birth of Christ. It passed again when Nero was Emperor; again when the first of the Antonines had just begun his pacific reign; again when the Goths were preparing to attack Rome, and yet again in the days of Diocletian. The advancing Huns beheld its transit in the year 373, and it was blazing in the sky when the great King Attila was defeated at Chalons in 451. Belisarius may have watched it as it swung across the heavens just after he had begun his victorious career in 530. It passed again when Mohammed was still worshipping the idols of his fathers in 608. The world saw the great index in the firmament again in 684, in 760, in 837, in 912 and in 989. It was on the noon mark for William the Conqueror in 1066. It returned in 1145; in 1223 it was thought to have predicted the death of Phillip Augustus; in 1301 it was watched with astonishment from Iceland to China; in 1378 Chinese and Europeans once more recorded its transit in their annals. We have seen how Islam and Christendom were terrified by it in 1456. It was back again in 1531 and 1607, and when in 1682 it shone once more in the sky the man had come who was to read its riddle and solve its mystery.

Is it possible to look forward to the re-

turn of a comet having such a history as this without feeling that the proper field of human interest is not limited by the narrow round of the earth?

The Compass Plant.

"Among the many wonders of the Western plains," said Garrett C. Hughes of Boulder, Colorado, "nothing strikes the traveler of a scientific turn of mind with more surprise than the 'compass plant.' The leaves of this singular plant are magnetic and its petals point constantly to the north. These wonderful prairie guides have on numerous occasions proved to be an inestimable benefit to travelers who strayed away from their camp and companions and found themselves lost on the plains. In 1860, while on my way to the Rocky mountains by a wagon train, a party of us, who had left camp on a hunt for antelope, lost our way owing to a dark, stormy night overtaking us. We knew that our train was camped about ten miles to the northwest of where we were thus overtaken. The night was as dark as pitch, and we were beginning to be alarmed, when one of our number happened to think of the compass plant and its singular peculiarity. We at once dismounted and groped about in the dark till at last our hands came in contact with the familiar leaves of the plant. It was but a short calculation till we turned our horses' heads in the right direction toward the camp, which we had the satisfaction of reaching in about two hours, but not until we had dismounted several times to feel among the leaves of this friendly guide to make sure of our course."—St. Louis Globe-Democrat.

The New Battle Ships.

The naval stability board has completed and submitted to the Secretary of the Navy its report upon the stability of the battleships Indiana, Massachusetts and Oregon. Practical heeling or inclining tests were made to ascertain the behavior of the vessels under all possible conditions of load. The result is highly gratifying to the department, for it justifies in all respects the designs of the vessels, and shows that they are superior to any warships afloat of corresponding size. The calculations of the bureau of construction, when the designs of the vessels were completed, showed that they were to have, with 400 tons of coal aboard and all weights, a total estimated weight of 10,093 tons. The actual weight or displacement was 10,162 tons, a variation of only two-thirds of one per cent. The designed draught was 24 feet; the experiments show that it is actually from 23 feet 11 inches to 24 feet. The excess buoyancy was to be 195 tons; it was actually 126 tons. The metacentric height was to be 3 feet 5½ inches; it was 3 feet 4¼ inches.

A Curious Formula.

The following formula will enable you to determine the day of the week of any date: Take the last two figures of the year; add a quarter of this, disregarding the fraction; add the date of the month, and to this add the figure in the following list, one figure standing for each month, 3-6-6-2-4-0-2-5-1-3-6-1. Divide the sum by seven, and the remainder will give the number of the day in the week, and when there is no remainder the day will be Saturday. As an illustration, take May 10, 1894. Take 94, add 23, add 10, add 4. Divide the sum by 7. The remainder is 5, and the day is Thursday. Or take to-day, add 94, 23, 9, 0. Divide the sum by 7. There is no remainder, showing the day to be Saturday.

WHERE telephone wires are overhead the speed of transmission is at the rate of 16,000 miles a second; through cables under the sea the speed is not more than 6000 miles a second.

Silver Dollars and Silver Bullion.

The purchasing clause of the Sherman Act called for the purchase by the Government of 4,500,000 ounces of silver bullion each month at the current or market price. This was paid for by the Government in special treasury notes. As the price of the bullion fluctuated, the volume of these notes was never the same any month, although the amount of bullion purchased each month was practically the same. From July, 1890, until the repeal of the Silver Purchasing Act, something less than \$154,000,000 of these special treasury notes were issued, and the great mass of silver bought therewith now lies in the Government vaults. The bullion would coin 209,000,000 of our present silver dollars, which contain each 371.25 grains of pure silver. The bullion value of our silver dollar averaged 81 cents during 1890; 76 cents in 1891; 67 cents in 1892, and ran down to about 60 cents in 1893, and has averaged less than this during the first five months of the year. At the present market price of silver bullion the \$154,000,000 treasury notes issued to buy bullion in 1890-91-92-93 would purchase enough to coin about 300,000,000 standard silver dollars. The bullion on hand will coin \$55,000,000 standard silver dollars in excess of \$154,000,000 treasury notes issued to purchase it. The act authorizing the purchase of this bullion gave the Secretary of the Treasury power to coin it, and the notes issued for its payment were made redeemable in either gold or silver. Running at full capacity it would take the Government months several years to coin all this bullion into dollars. The Bland bill, which passed Congress and was vetoed by the President, intended to expand the circulating paper currency represented by this mass of silver from the outstanding issue of treasury notes to an amount \$55,000,000 greater, by treating the whole of it as if it were a deposit of coined silver dollars, for each of which a corresponding paper dollar should be sent out.

That Defective Armor Plate.

The defective armor plates shipped by the Carnegie Company to the National Government have been the cause of considerable gossip, and the usual newspaper cataract of mud and abuse. Conjecture has had the usual free use of printers' ink, and animosity has had a delightful opportunity to prejudice public opinion. Facts have been manufactured like bottles, to be on sale to-day and broken to-morrow. Truth, like the traditional needle in a stack of timothy, has been hard to find, and until this is located, all prejudging and conjecture is simply on par with guessing the number of peas in a pod. To any fair-minded man it is not reasonable to suppose that the Carnegie Company would connive at tricking the Government and jeopardize their reputation and honesty by a few defective plates. This would be selling Esau's birthright for less than a mess of pottage. That a trick has been played on the company for purposes of revenge is possible, yet not fair to assume without evidence. It may rather turn out to be an instance of oversight or carelessness. Investigation will probably remove the skin from the sore. It is, however, by no means commensurate to the manners of the times that even a national reputation is no protection against scandal mongers, rogues, conspirators or even such small fry as the political or commercial sucker.—Age of Steel.

New Naval Militia Flag.

The Secretary of the Navy has approved a design of a special flag for the naval militia. It has a field of blue, in the center of which is a division of yellow showing a blue anchor. This flag will be displayed on all warships engaged in naval militia drill and will be used by the militia of the various States.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt, will be very desirable in the hands of many.

Tables of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Sintering; Cupellation; Weighing the Bead; Fuming; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Tables of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Notes.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc.

The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is reprinted by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market St., San Francisco.

Golden Relics in Mexico.

In one of the oldest ruins in the State of Oaxaca, Mexico, a number of very rare and interesting images, found in metal, have been uncovered. The images represent people of oriental appearance and dress, as well as priests in their robes of sacrifice. They bear hieroglyphics of unknown characters and are elaborately wrought, with fine art lines shown in every curve. The images found thus far are of gold, either wholly or in part, and are coated with some unknown enamel, which has preserved them from all harm in the many years they have been buried in the soil.

AN INQUIRY was last year sent to the astronomers of different countries concerning the desirability of beginning the astronomical day at midnight on and after January 1, 1901. The present reckoning from noon to noon, 12 hours behind the civil day, has serious disadvantages. The change was favored in 107 replies and opposed in 63.

SYLVANITE is a native telluride of gold, silver and sometimes lead. It occurs crystallized and massive, of a steel-gray to silver-white color and brilliant metallic luster. The crystals are often so arranged in parallel position on the rock surface as to resemble written characters; it is hence called graphic tellurium or graphic gold.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

Regarding the famous Gwin mine, which up to twelve years ago had paid \$2,000,000 in dividends, the *Amador Ledger* says: When it had been worked to a depth of 1500 feet there was a cave in the shaft, and ever since the great mine has been untouched. F. F. Thomas, the chief promoter and stockholder of the company which is to reopen the mine, has 20 men on the preliminary work, and as soon as this is done a new shaft will be started on lower ground and sunk 1400 feet, opening the vein to a depth 300 feet below the old workings.

ENTERPRISE.—*Record*: The superintendent of the Bay State mine reports that since starting the crosscuts at the four and five hundred levels two stations have been cut. No. 5 crosscut has been run a distance of 35 feet, and No. 4 crosscut is in 32 feet, with ground of the same character in both crosscuts as met with in the shaft. The track in the shaft has been fixed for the skip, and is now in good working order. The pump is working satisfactorily, making but one stroke in one and one-half minutes, and raising the small quantity of 13 gallons of water per minute. The contractors are bearing every energy for the final completion of their contracts, which is looked forward to with increased interest as they near the great footwall ledge. If this idea is correct, this will be the objective point on the mother lode of Amador county, as this is the first development made north of the great bonanza mine of Plymouth.

The shaft of the Pioneer mine at Plymouth is down 300 feet, and about 120 feet below the drain tunnel, and although the ledge is small it is remarkably rich. It is the intention of Dr. Boyson, the owner of the mine, to open a station and run crosscuts in the near future, and if the development proves satisfactory he will erect a 10-stamp mill right away.

Butte.

RICH STRIKE.—*New Era*: A rich strike has been made in a new ledge owned by the Denver Company, Messrs. Price & Lane. The rock, it is said, will mill \$40 to the ton, and there is considerable of it in sight. The new discovery was made about a quarter of a mile from the mill, but the ledge is so situated that the ore can be delivered to the mill at very little expense. The Denver is considered one of the best mining properties in the Forbestown district.

Mono.

The Bodie *Miner* says: "It is confidently expected that Bodie will be a better camp during the summer than it has been for several years, and business men generally seem to take a hopeful view of the outlook. Bodie has enriched the world to the extent of \$20,000,000 in gold, and there is a lot more of the yellow metal stored away in the hills. It is only a question of time when it will be extracted and added to the rushing marts of trade."

Nevada.

FOUND THE LENOE.—*Herald*: Prof. T. B. Gray, who is having the old Buckeye mine in Willow valley put in shape for working, has found the ledge. It is a large vein and looks pretty good. Some 30 years ago the mine was worked and some 1000 tons of rock were taken out and milled. It is said to have run all the way from \$7 to \$45 a ton. Prof. Gray believes the Buckeye to be a true fissure vein. It is in porphyry, on the slate and granite contact.

STRUCK IT RICH.—*Herald*: John Fippin of Rough and Ready has had a test crushing of rock from the Fippin mine made at Locklin's mill, in this city, which yielded \$191.70 per ton. How is that for a mill test? Mr. Fippin discovered this ledge on April 23d. He has sunk ten or twelve feet, and now has a ledge ten inches wide. He struck water at that depth. Considerable prospecting is being done around Rough and Ready this year, and Mr. Fippin's strike will give it a new impetus. Both the Mistletoe and Osceola mines are likely to change hands soon, in event of which it is understood that machinery will be put up and some real mining done. Rough and Ready was a flourishing mining district once, and, like many others, it may come to the front again. Residents say that it would pay some one to erect a custom mill there. An express office is also needed.

Grass Valley Union. The directors of the Badger Hill quartz mine have decided to put a new pump at work and to push work as fast as possible. There is a good ledge varying from one to two feet in size, which averages over \$20 per ton, exclusive of sulphurets. It is contemplated to erect a mill on the property before long. Paul Quick Jr. of this city has gone to Badger Hill to superintend operations.

Grass Valley Telegraph. Supt. J. A. Conlon let a contract for sinking the shaft at the Conlon mine and work will be commenced immediately. The shaft is now down 200 feet and the company intend sinking it 300 feet deeper without stopping. John McLaughlin and party secured the contract. The location of the mine is good, being on Osborn Hill, surrounded by fine mining properties. The company intend to see the bottom of it.

Saturday, the result of the sulphurets cleaned up by Mone. Colliot, from the last crushing made on Wisconsin rock, was favorable indeed. There were 21 tons of sulphurets saved, and the result was that they paid \$110 per ton, or \$2310. The miners who have the mine leased say that it is looking well.

Herald: The Mineral Hill Mining Co., whose mine is located at Mineral, about three miles thence of Spenceville, are preparing for their

new smelting plant, which is now on its way out from the East. By their improved method of smelting they expect to save all the gold and silver in the copper ore, and as a guarantee that the machinery will do this the company is to be allowed to run the plant for 30 days on trial.

The Jackson Mining Co., whose claim adjoins the Mineral Hill, is taking out rich ore, and the latter company has signed a contract to take 100 tons per month from the Jackson, for reduction, said contract to begin June 1st. If Mineral Hill turns out well, things will be lively down there this summer, as both mining companies own valuable property and are able to work their mine to their fullest extent.

Placer.

GOON PROSPECT AT DUTCH FLAT.—*Colfax Sentinel*: During the past week some good gravel has been struck in the shaft sunk at the lower end of the town of Dutch Flat. The shaft is down 87 feet, and bedrock was struck at about 83 feet. A drift is being run toward the east, in which direction the bedrock is pitching. Last Friday, good prospecting gravel was found at a distance of about 30 feet from the shaft. A cleanup of the gravel taken out during the past week was made Tuesday of this week, and although a greater part of the dirt washed consisted of bedrock, it went a dollar a carload. The gold is all regular coarse channel gold; and if there is much of a channel of it, old Dutch Flat will once more become a lively mining town. The indications at present are very favorable, and the prospecting work is being pushed ahead as rapidly as possible. The gravel is blue and in some places is cemented. The bedrock is still pitching, and it will be some time before the true nature of the channel will be known.

Columbus Waterhouse of the Big Dipper mine, in response to a query concerning affairs at the mine, said they had recently added about 25 men and were running two breasts. They expect to open a new breast this week, which will necessitate the addition of 15 or 20 new men to the force now employed.

Plumas.

NORTH FORK MINING NEWS.—*National Bulletin*: The King mine, owned by Fred Scott, continues to produce large returns from the ground being extracted.

Adjoining the King mine is that owned by Angus Cameron. It embraces about 3300 feet of the ancient channel running through Big Flat. Mr. Cameron tapped it with a tunnel at a point about 500 feet from the mouth of the tunnel, and after he had made an upraise of 36 feet. This is at the lower end of the channel, which has been cut across and found to be 70 feet wide from rim to rim. Mr. Cameron is getting considerable gold from the gravel which is now being extracted.

The Glazier mine has been bonded by Dr. J. P. Welch, and it is understood that he will tap the channel with a tunnel at the lower end of the claim. It is estimated that this tunnel will be between 400 and 1000 feet in length.

Lee, McMullen and Bamrick are preparing to wing-dam the river below the Wildcat to work the present river channel.

Harry Ratford is taking out some money at Bamboo.

Dick White will wing-dam the river and resume work on the claim from which he has taken considerable gold during the past three years.

Leinbart, Mori & Akile will start to work on the Kirkham claim as soon as the water becomes sufficiently low. They have the property leased of Savercool & Duryea.

Mandeville & Co. are driving a tunnel on the Cub quartz mine. They are also prospecting a quartz discovery lately made by them near the Dick White claim. This Mr. Cameron considers one of the best quartz prospects in the country. It is about 400 feet above the present river bed. The ledge is three feet wide and the quartz is high grade. If at a depth it proves of the same quality as that near the surface, it will certainly become a big mining proposition.

Joe Boreini & Co. are at work in the Bunker Hill gravel mine, which is paying them \$3 per day to the man.

Opposite Marion Flat, Geo. Scott is operating a gravel mine, which is paying from \$4 to \$6 per day.

At the lower end of Yankee Bar, Stephen Dean is fitting up a claim to be worked with a derrick.

Shasta.

Democrat: Six carloads of lumber for the Quartz Hill Mining Co. are being unloaded at the depot. The Quartz Hill Co. is doing an immense amount of development work on the mine.

Siskiyou.

Yreka Journal: The Van Vactor & Staples mine on Hungry creek has developed into a splendid property, being an eight-foot ledge, with \$20 rock free gold, five per cent sulphurets, that goes \$490 per ton. It would take a big sack to buy it now.

The district known as Fool's Paradise, between Shasta and Klamath rivers, is coming to the front as a mining camp, a recent discovery being bonded for \$10,000. A corporation has been formed, to be known as the Fool's Paradise Prospecting, Mining and Improvement Co., with the object of developing properties in that new camp. B. G. Reeder, president; E. L. Hall, vice-president; W. B. Edmundson, secretary; Charles Bennett, treasurer; Franklin Howland, cashier; A. B. Jenkins, general manager and superintendent.

Trinity.

MINING DEAL CONSUMMATED.—O. M. Loveridge has bought the Lappin property, a few miles from Minersville. The property consists of a main ditch of five miles in length and branch ditches of about fifteen miles, together with water rights which virtually control all the mining around in this vicinity; in fact it is the

key of the entire situation around this camp. The diggings of Mule creek, Strophe creek, Digger creek and Greenhorn, with numerous gulches and thousands of acres of aridiferous gravel, are covered by the waters included in the purchase and upon which they depend. The purchaser will take possession on the 1st of October.

Tuolumne.

MINING NOTES.—*Independent*: Mr. Chute is actively engaged in developing his Rappabannock mine. His shaft is sunk 22 feet. The slates intersected are black metallic and the vein matter is coming in. We hope soon to chronicle a rich strike. The county surveyor, Carroll McTarnahan, has been making surveys for water power and locating the lines on Mr. Chute's vein lands, which he has acquired by United States patent. This is a valuable adjunct to his property.

The old Joe Hooker mine, near the Parole, which has been shut down for years, will shortly commence active operations. A new two-compartment shaft has been sunk about 200 feet from the old works, and is now about 45 feet deep. The owners are awaiting their new engine, which is expected this week, when the work of sinking will be resumed. The country rock being soft, the miners are able to make rapid progress. The carpenters have completed a new gallows frame, in addition to other work done on the mine.

The Parole mine, situated at the head of Sullivan's creek, is now running at full blast. A force of men, working day and night, is making rapid progress. The hoisting works, blacksmith shops, etc., are completed and ready for use. The water in the old shaft, which is 100 feet deep, has been taken out and levels run at this depth on the vein, about 40 feet both north and south. The owners of the property are hopeful of the best results.

The Rawhide is getting the water, which has been a great annoyance of late, under control, and will soon commence active operations in the mine.

The Alameda crosscut is being rapidly pushed ahead to the footwall. Good milling ore has been intersected, and the best of results are anticipated.

We understand the Tarantula, on the mother lode, is likely to change hands in a day or two.

NEVADA.

Washoe District.

Following are copies of the official letters of Comstock mine superintendents filed at the companies' offices:

CON. CAL. & VIRGINIA.—1650 level.—From the top of the south drift No. 1, on the sill floor of this level, in the ore body recently found, an upraise has been carried up 6 feet and this opening has been extended out to the east a distance of 6 feet—all in ore of high grade, with signs of lower grade ore in the top. The south drift No. 3, 26 feet under the south drift No. 1, has been extended 9 feet, the first five feet in ore which will average \$50 per ton. The length of this drift is 35 feet, of which 31 is in ore. The face is in quartz with some porphyry carrying a low assay value. At the mouth of this drift an upraise has been carried up and connected with the south end of the south drift No. 2—in ore of good quality.—The south drift No. 4—in the 1700 level—has been opened and repaired to a point 112 feet distant south from the winze.

The ore extracted during the week amounted to 67 carloads—about 66 tons—the average assay value of which (per car samples) was \$95.42 per ton. The largest portion of this ore came from the south drift No. 3 and the remainder from the opening above the south drift No. 1.

On the 1000 level—the Rule drift.—From upraise on the east side of the main drift at a point 585 feet south from the shaft station, at a point 95 feet up, a northwest drift has been advanced 38 feet; and from this drift at a point 20 feet in, a west crosscut has been advanced 15 feet; face in porphyry. The west crosscut from the main drift, 370 feet south from the shaft station, has been advanced 50 feet; total length 95 feet. At a point 235 feet south from the shaft station, an east crosscut from the main drift has been advanced 23 feet; face in porphyry carrying lines of quartz.

UNION MINA.—900 level.—The Union Con. and Sierra Nevada joint north drift which was run from the joint west drift at a point 1520 feet west of the shaft, has been extended during the week 11 feet; total length 404 feet; face in hard porphyry. The joint south lateral drift from the joint west drift, at a point 1520 feet west of the shaft, has been extended 21 feet; total length 31 feet; face in clay and porphyry.

MEXICAN.—1465 level.—From the top of the upraise which was carried up 45 feet above the sill floor of this level at a point 40 feet west from the main north drift and 100 feet north from the south line of the mine, a west crosscut has been advanced during the week 25 feet; in porphyry and etreake of quartz of nominal value.

As joint work with the Ophir Company, making repairs in the incline shaft which extends downward from the 1465 level station of the Ophir shaft.

OPHIR.—1465 level.—The drift run south from the crosscut run west from the main north drift, at a point 219 feet in from the mouth of the crosscut, has been extended during the week 14 feet; total length 134 feet; in a porphyry formation carrying lines of quartz of low assay value.

Have continued jointly with the Mexican Company the work of making repairs in the incline shaft, which extends downward from the 1465 level station of the Ophir main shaft.

CENTRAL TUNNEL.—The west crosscut started from the drift run north from the old Mexican shaft on the tunnel level has been extended 29 feet; total length 50 feet; continuing in porphyry and clay. From the drift run north-

weeterly from the shaft, 56 feet above the tunnel level, at a point 60 feet from the shaft, a west crosscut has been advanced 50 feet; face in porphyry.

SAVAGE.—On the 1050 level east crosscut No. 1, started in the north drift, at a point 45 feet from the station, was advanced 10 feet, making its total length 70 feet; face in ledge formation. Finished repairing and retimbering the main south drift on this level. The upraise from the north drift is advanced 48 feet; top in quartz giving fair assays. On the 1100 level west crosscut No. 2, started from face of the north drift, was advanced 18 feet; total length 32 feet. We are repairing the main south lateral drift on this level. During the week we have hoisted 26 cars of ore. Car samples average \$27.75 per ton.

HALE & NOACROSS.—900 level.—Advanced southwest drift 5 feet; total length 259 feet. Have started a west crosscut from the end of this drift and advanced the same 5 feet; face in porphyry.

1100 level.—East crosscut from the end of main south drift was advanced 10 feet; total length 33 feet; the face is in porphyry. All work was stopped at the mine for one day the past week.

ANDER.—420 level.—The upraise from the west crosscut that connects the north lateral drift with the main north drift has been carried up 8 feet; total length 34 feet; formation quartz and porphyry.

BAST & BALCHER.—200 level.—Have started on our northwest boundary a northwest drift, 1115 feet from main northwest drift, and advanced same 14 feet, passing through porphyry and quartz giving low assays; total length 30 feet. 800 level.—Northwest drift, started in crosscut in west crosscut No. 2, 415 feet from main north drift, has been extended 12 feet, passing through quartz and porphyry; total length 33 feet.

GOULD & CUNAY.—On the 200 level west crosscut No. 5, 1115 feet from northwest drift, have started a drift in a face of quartz and advanced the same 15 feet. All work has been discontinued in face of west crosscut No. 5.

OCCIDENTAL.—From the west ledge above the 400 level we continue to extract about 8 tons of ore per week of the average assay value of \$12 per ton, as per car sample. Milled during the month of May 132 tons of ore and slimes, and produced bullion valued by assay at \$2428.34.

KENTUCK.—The south drift from the east crosscut on the 1035 level is in 60 feet and continues in quartz with spots of pay ore. The south drift from the Yellow Jacket incline has been extended 8 feet; total length 100 feet; face in low-grade gold ore.

ALTA.—We have finished the winze station, and sinking was commenced this morning. The south drift from the north raise has been extended 14 feet; total length 80 feet. There is 10 or 12 inches of fair-grade ore in the face. The average value, according to car samples, is \$33.62 per ton.

IOWA.—During the past week—sinking winze in fair-grade gold ore.

WEST CON. VA. & CAL.—During the past week the west crosscut run from a joint 320 feet north of the shaft station on the 1100 level, has been extended 31 feet, and is now in a total distance of 870 feet. The flow of water has somewhat increased. The face is in quartzite of a softer nature, carrying seams of porphyry and quartz.

ARIZONA.

A FINE SHOWING.—*Record*: The Harqua Hala Gold Mining Company Limited of Arizona is making a fine showing. The superintendent reports as follows: The mill started on March 31st, when it was shut down for the cleanup. The following figures represent the month's operations: Ore crushed, 2928 tons; amalgam cleaned up (estimated), \$37,000; working expenses, revenue account, \$10,400; estimated profit for the month, \$26,600. To this is added \$1472, the net yield from amalgam and coarse gold from bar No. 4, November account, and \$3000 from profits from general store for six months ending March 31st. The average loss in tailings was \$2.69 per ton.

Tombstone Epitaph: Claude Blimbangh came down from Tip Top, a mine near Phoenix, recently with a nine-hurro train laden with rich concentrates from Fred Blumb's mines. The value of the cargo was placed by guesswork at \$100,000. The concentrates were shipped to the smelter at El Paso.

THE UNITED VANAS MINES.—The *Journal-Miner* publishes an extended description of the United Verde Copper Company's mine and plant at Jerome. The mine is said to be one of the largest and richest bodies of ore in the country. The reduction plant consists of three water-jacketed furnaces and one reverberatory furnace, with an actual aggregate capacity of 250 tons daily. Another 150-ton furnace and three converters are to be added this summer. The ore has first to undergo a roasting process, which requires from six weeks to three months. There are 15 miles of 18-inch gauge railroad in operation. The bucket tramway has finally been made to work satisfactorily for a distance of five miles with one transfer station. The offices, smelter and a portion of the mine are lighted by electricity. A larger electric plant is to be put in to light the mines and town of Jerome, and run portions of the new machinery. The mine will also be equipped with a large and powerful double-compartment hoist, the machinery for which is now on the ground.

COLORADO.

STRIKE OF SYLVANITE.—Colorado Springs *Gazette*: As nearly metal as sylvanite ore can be when found in quartz is the character of some of the stuff taken from the Gold Dollar mine, on Beacon Hill, in the last three days. In the drift at the bottom of the shaft 85 feet from the surface an upraise was started on

Wednesday. It was noticed that with each foot the quartz improved in grade and everybody about the property was in great glee; but glee was turned into ecstasy and joy when a piece of sylvanite two inches thick, several inches long and four or five inches wide was picked from the wall, the value of which alone is way up in the hundreds. After that great care was used in breaking the rock, and tonight about 80 pounds of this remarkably rich ore had been found, and it was all brought to town and locked up in a safe. Its value is variously estimated at from \$3000 to \$6000. The camp is in a fever of excitement over the strike.

A LITTLE PROFIT STILL.—Idaho Springs News: For all that the price of silver is so low, many of the mines around Georgetown that produce galena, with a small per cent in silver, are being worked with profit, the bodies of ore that are uncovered being so immense. A vein of solid galena in the Seven-Thirty mine is 12 inches thick and is now exposed for a distance of 100 feet.

MONTANA.

THE GOLDEN SUNLIGHT.—Butte Inter-Mountain: It is rumored that the Golden Sunlight mines, recently sold for half a million dollars by the American Developing and Mining Company to a New York syndicate, are likely to change hands again for a million dollars.

From recent developments it is certain that half a million dollars was cheap for these properties. The ore is said to be unlimited in extent, and, judging from the extensive improvements being made, the company has every confidence in the permanence of the ore bodies. The mineral-bearing rock closely resembles that found in the Butte copper belt, and though the Camp Golden ore carries both silver and copper, its principal value is in gold. The vein now being worked is in a hill that looks very much like the Mountain View or Anaconda hills. The ore is being taken out through a tunnel near the top of the hill, and is raised through a shaft in the tunnel. At present operations are confined to the east side of the hill, though the employees live on the west side and have to cross over the top of the hill to their lodgings. On the west side there is a shaft and a new hoist. A boiler has recently been placed in position at this point to supply steam to operate the hoist.

A tramway 860 feet in length is now in successful operation at the mine. It is operated with two cars and is built at an angle of about 70 degrees. The ore bins at each end of the tramway are easily kept filled with ore. The force of miners employed is quite small as yet, but all that can be utilized are at work. At the present time there are 48 men on the payroll. Most of these are carpenters and builders, who are working like hammers.

Bunk houses for men, boarding houses and other necessary buildings are being constructed with all possible speed. Men are engaged in driving a tunnel which will tap the vein at a depth of 800 feet. This is now in 200 feet. Another gang of men is preparing a location for an air compressor. Stone masons are building a large-sized powder magazine. Laborers are employed on the wagon road from the mine to Clark's Spruce as the railway station has been named. Taken altogether, Camp Golden is the busiest mining camp in the State, and gives promise of a great future. It lies about three miles north of the railroad, and is reached by a circuitous and steep railway. As soon as accommodations are made the force of miners will be increased. Miners are camped all around the neighborhood awaiting orders to go to work.

The first ore shipment in bulk by the new company was made Friday, May 18th. The ore wagons hauled freight from the railroad spur and return with ore. Last week five carloads of the ore were shipped to Helena. The ore was second-class and is said to be worth \$1000 to the car. Ore shipments will continue regularly, the company now being in condition to make the mine pay for all the improvements being made.

The great drawback at the mines at present is the water supply. Water for domestic purposes is being hauled to the mine from Jefferson island at a cost of \$5 per day. The company has secured a spring in Soap gulch, 9000 feet from the mines, and it is proposed to pipe this.

Thomas Stairbird, formerly of the Granite Mountain mine, is in charge of operations at the mines. The company has plans perfected for a large concentrator, which will be located on the slough of the Jefferson river. This will be about half a mile from the railroad. An 80-horse power boiler is now being hauled up to the mines. The boiler has 50 flues and weighs 18,680 pounds. It required 12 horses to haul it. It will take several days to get this boiler to its destination.

Within 60 days, it is said, the company will have 300 men on the payroll. All miners who have seen the Golden Sunlight are unanimous in pronouncing it a great property.

NEW MEXICO.

GRANT COUNTY.—Enterprise: The big strike reported on the 625-foot level of the Graphic mine at Cook's Peak has proved of very great extent as far as developed, with the prospects and indications that it will open an enormous body of ore. After running a crosscut 115 feet from the shaft the vein was cut with a body of ore about four feet in width. Since then a drift has been driven along the vein, with an ore body from two to six feet in width the full length of the drift. The ore assays about 40 ounces in silver and 40 per cent lead. On the 500-foot level this same ore content was followed for 500 feet in length, and from present indications it will be fully as long on the 625-foot level. In the bottom of the drift the ore is fully as good, and indicates that other levels below can be opened with as good results.

Coast Industrial Notes.

—The season's seal catch has been the largest for many years.

—Men are reported working on Lassen county ranches for fifty cents a day.

—Fresno county is about to build a canal to tide water at an expense of \$150,000.

—It is proposed to light the New City Hall at a first cost of \$75,000, and \$15,000 annually thereafter.

—Fresno county is shipping wine to Liverpool via Cape Horn. The freight is about seven cents a gallon.

—Members of the Consumers Ice Company of this city say they can manufacture ice for \$2.50 per ton.

—The German Government this year has ordered 200,000 gallons of California brandy for use in hospitals, choosing it in preference to French.

—The extreme high water in the Columbia has greatly damaged the salmon fish interests, owing to the sweeping away of the fish wheels.

—The U. P. mortgage at Portland on the Oregon Railway and Navigation Company is about to be foreclosed because the bond interest has not been paid.

—From the slow way in which work is being done at the Union Depot at the foot of Market street, it is evident this century will not see its completion.

—The Senate has voted to put manufactured as well as rough lumber on the free list, which will be eminently acceptable to British Columbia lumber men.

—Several English fire insurance companies with San Francisco agencies will decline future American business, the alleged losses making necessary their withdrawal.

—J. J. Consins is about to build a new dry dock between North's ways and Hunter's Point. It will take a 2500-ton vessel. The Merchants' dry dock at the foot of Spear street is also to be rebuilt.

—W. B. Bonnin has sold his St. Helena winery to C. Carpy. It cost him \$600,000, and it is thought he got that for it. The cellar is the largest in America and has a capacity of 3,500,000 gallons.

—Wells, Fargo & Co. propose to prevent future train robberies so far as possible, and are having twenty-five cars fitted up for the run between here and El Paso, Texas, with chilled steel safes and other protection against burglars.

—The Northern Pacific Company is about to build new coal bunkers at Tacoma, nearly treble the size of any other bunkers in the Northwest, having a capacity of 15,000 tons, costing \$60,000, and enabling a 5000-ton cargo to be loaded in eight hours.

—The clearings at the clearing house in this city during May, '94, and May, '93, compare as follows:

	'93.	'94.
Clearings	\$69,718,702 93	\$60,131,580 42
Balances	8,664,515 51	7,603,282 77

—Representative Doolittle of Washington has introduced a bill to appropriate \$100,000 for ascertaining the subterranean water supplies in Idaho, Montana, Washington and Oregon, lying east of the Cascade mountains, and ascertaining the localities at which artesian wells can profitably be dug. It is proposed to have the work done by the Geological Survey.

—The Colfax Sentinel reports that water was turned into the new South Yuba canal last Wednesday, and for the first time in the history of the divide the residents will be able to secure water for irrigation purposes and to furnish power to run quartz mills. The South Yuba Company has spent several hundred thousand dollars in these improvements, and they intend to eventually furnish Sacramento with pure mountain water.

—S. J. Klein, a Roumanian, is conducting negotiations for the purchase of 200,000 acres of land belonging to the Mitchell estate in Merced county. If the deal is carried through, 14,000 Roumanians will settle in California as colonists. These Roumanians are of German descent and live in Bessarabia. They are dissatisfied with the arrangement whereby Bessarabia was ceded to Russia, and want to get away from Russian rule.

—Frank Johnson, of the Johnson-Locke Mercantile Co., would like to see California merchants and manufacturers reach after the South African trade, which is great and growing. He will dispatch the large iron steamer Santa Clara for Capetown direct about July 1st, provided 300 passengers are booked. There is good business to be secured with that section, now nearly altogether in English hands, and a direct line to the South African gold fields is in direct line with securing such business.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market St., S. F.

FOR THE WEEK ENDING MAY 29, 1894.

520,558.—CALIFRER—Adra F. Brockway, Pasadena, Cal.
520,538.—BUCKLE—C. A. O'Gier, S. F.
520,670.—WATER PUMP—Day & Hunter, S. F.
520,781.—CONE CLASPER—H. Fisher, Sacramento, Cal.
520,732.—PENCIL SHARPENER—H. Fisher, Sacramento, Cal.
520,563.—PROPELLER—O. B. Gentry, Vallejo, Cal.
520,689.—WRENCH—H. Krebe, San Pedro, Cal.
520,697.—ELEVATOR—W. H. McCoy, Los Angeles, Cal.
520,443.—CAR COUPLING—W. S. Miller, Spokane, Wash.
520,541.—ADVERTISING WAGON—J. N. Russell, Los Angeles, Cal.
520,663.—PEN FENDER—B. F. Smi b, Represa, Cal.
520,501.—CLOTHES DRIER—E. S. Sutton, Snohomish, Wash.
520,480.—KITCHEN CABINET—Minnie S. Thomas, Waterville, Wash.
520,549.—PRESERVING EGGS—F. M. Underwood, Pasadena, Cal.
520,719.—BLAST FURNACE—Walker & Murphy, Globe, A. T.
23,310.—DEIGN FOR SPOON—C. S. Thompson, San Diego, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ENVELOPE.—George H. Martin, San Francisco, Cal. No. 519,864. Dated May 15, 1894. This invention relates to improvements in letter envelopes. The object is to provide an envelope for the enclosing of letters and papers; an improved method of cutting the paper so as to economize the stock from which the envelopes are cut; an improved method for overlapping and joining the end flaps upon opposite sides, so as to make a double thickness of material and make the envelope opaque, and a safety device for the envelope when sealed.

GUIDING DEVICE FOR DISCHARGE NOZZLES.—Charles F. Rodin, San Francisco, Cal., assignor of one-half to Adrian Merle and Andrew Rudegar, San Francisco, No. 520,222. Dated May 22, 1894. This invention relates to a device for guiding the stream from discharge nozzles to prevent a rotary motion thereof, and to maintain the body of water in a solid condition after it leaves the nozzle. The object is to provide a device which will correct the tendency of water to rotate and break into spray when it leaves a discharge nozzle under pressure. It is especially applicable to hydraulic nozzles of all descriptions which are used to wash banks of earth, and to the nozzles of fire engines, and in cases where it is desired to throw the solid stream of water to the greatest possible distance before it breaks. It consists essentially of interior prismatic tubes formed by rectilinear plates extending longitudinally through the pipe, to the end of which the discharge tip is connected, said plates being arranged to form enclosed triangular or rectangular spaces.

LEDGER INDEX.—Thomas A. Uren, Prineville, Oregon. No. 520,095. Dated May 22, 1894. The object of this invention is to provide a simple and convenient ledger index so that the accountant may, with convenience and a minimum loss of time, refer to any particular name and find the page of the index of the account required. It consists of a box or frame having a plain surface, a vertical series of slots in the front, a series of spring-actuated rollers within the box, strips or sheets of paper bearing references wound upon the rollers with the free ends projecting through the slots in the frame, crossbars secured to the free ends with indexed pull tags secured at or near the center. These bars have their ends projecting beyond the end walls of the slots to form limiting stops, and there are elastic cushions on each side against which the ends of the bars strike when they are drawn in by the action of the spring rollers. The frame or box has suitably formed irons at the bottom serving as feet, so that it may be attached to a desk or support. The names of the various customers or accounts, with the number of the page on which the account in the ledger is to be found, are written upon the sheets arranged alphabetically, and as many letters may be placed upon each page as the size and convenience of the apparatus will admit. It is only necessary for the accountant to pull out the broad sheet having the initial letter of the account he wishes, to find the name and page, and as soon as released the spring roller draws it inward and winds it up again.

PEN FENDER.—Brainard F. Smith, Represa, Cal. No. 520,663. Dated May 29, 1894. The object of this invention is to provide a means for protecting the edge of a ruler from the ink which is carried by the point of the pen when the latter is used for drawing lines, and to thus prevent the ink from being smeared upon the ruler and possibly transferred to the paper. It consists of a fender hinged at one end, adapted to be turned up into a vertical line by

the side of the penholder handle when not in use, or be turned down so as to stand opposite the point of the pen when it is to be used, and it is provided with a screw by which it is adjusted to and from the point of the pen at will.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower Engine and 45-horsepower Boiler, with Ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Assessment Notices.

OCCEANICAL CON. MINING COMPANY.—LOCATION of principal place of business, San Francisco, California; location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Trustees, held on the thirty-first day of May, 1894, an assessment (No. 16) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 6th day of July, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the thirty-first day of July, 1894, to pay the delinquent assessment, together with the costs of advertising and expense of sale. By order of the Board of Trustees.

ALFRED K. DUBROW, Secretary.
Office—Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

F. ORTON, Mechanical Engineer.

EXPERT DESIGNER of Special and General Machinery.
PREPARING PLANS of Steam, Air and Hydraulic Apparatus; Iron and Wood-Cutting Machines; Transmission of Power, Etc.

MANUFACTURERS OF

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Market Reports.

The Markets.

SAN FRANCISCO, June 7, 1894.

The usual weekly fluctuations in silver left little difference between the opening and the close. The London press is practically unanimous in the assertion that England is expected to reopen the India mints or lose the cotton goods trade with China and Japan.

New York Prices.

NEW YORK, June 7.—Following are the closing prices for the week:

DIVIDENDS FOR MAY.

The following local incorporations disbursed dividends during the past month:

Name.	Rate.	Amount.
Central Gaslight Co.....	\$1.00 per share.	\$20,000
California Electric Light.....	15c per share.	7,500
Edison L. and P. Co.....	8c per share.	10,666
Oakland Gas Co.....	20c per share.	6,000
Pac. Gas Improvem't Co.....	50c per share.	15,000
S. F. Gaslight Co.....	35c per share.	35,000
Contra Costa Water Co.....	50c per share.	15,000
Spring Valley Water Co.....	50c per share.	58,500
Atlantic Dynamite Co.....	40c per share.	12,000
California-Street Cable.....	50c per share.	5,000
Gary-Street Railroad Co.....	50c per share.	5,000
Metropolitan Railway Co.....	10c per share.	1,000
Alaska Packers' Ass'n.....	75c per share.	30,000
California Cotton Mills.....	\$1.00 per share.	6,000
Odd Fellows' Hall Ass'n.....	5c per share.
Pac. Auxiliary Alarm.....	5c per share.	1,250
Pacific Telephone.....	40c per share.	13,200
Sunset Telephone.....	25c per share.	7,500
Copper Queen Con. M. Co.....	25c per share.	50,000
Golden Rule Mining Co.....	2c per share.	5,000
Highland Mining Co.....	20c per share.	10,000
Homestake Mining Co.....	15c per share.	18,750
Omaha Mining Co.....	50c per share.	12,000
Standard Con. Mining Co.....	10c per share.	10,000

Total.....\$354,366

A summary of the dividends for the month compares as follows:

	1893.	1894.
Gas companies.....	\$ 84,000	\$ 94,166
Water companies.....	70,000	73,500
Insurance companies.....	1,500
Powder companies.....	19,500	12,000
Street railroad companies.....	10,000	11,000
Mining companies.....	176,100	105,750
Miscellaneous companies.....	24,200	57,950

Totals.....\$385,300 \$354,366

There was \$2,023,000 gold coined here in May; of that \$465,200 was paid in for duties and \$269,400 exported, leaving \$1,288,400 added to local circulation. During the five months from January 1 to May 31, the local gold coinage was \$9,760,000; there was paid in that time \$2,309,600, duties, and \$9,050,700 was exported, showing a loss to local circulation in that time of \$1,600,300.

During the same five months there was shipped from San Francisco specie as follows: Silver bars, \$2,311,905; Mexican dollars, \$1,750,552; S. American dollars, \$132,100; gold coin, \$9,050,700; silver coin, \$311,800; gold dust, \$200; currency and bonds, \$1,228,208; total, \$14,785,465. Of that amount \$10,147,107 was sent to New York, \$2,392,536 to Hong Kong, \$1,784,864 to Japan, \$329,008 to Central America, \$128,950 to Honolulu, and \$3000 to Samoa.

Mining Share Market.

SAN FRANCISCO, June 7, 1894.

Those who expected a steady appreciation in the price of stocks because they thought have been disappointed. Those who argue that the value of the mine has much to do with the current price of stock have also been disappointed. Low prices and little activity have characterized the week's business. Even the Virginia Enterprise says: "It is noticeable, however, that the more promising things look in the mines the more likely the price of stocks is to take a tumble."

The following illustrates the changes of the week:

MINES.	81	7

The Standard Con. had \$34,064.86 on hand on the 1st.

The Crown Point Mining Co. at its annual meeting, at which 70,800 shares were represented, elected the following officers for the ensuing year: C. L. McCoy, president; A. K. P. Harmon, vice-president; James H. Dobinson, J. P. Martin and James Newlands, directors. James Newlands was re-elected secretary and H. M. Gorham superintendent.

There were 73,160 shares represented at the annual meeting of the Seg. Belcher & Midas Con. M. Co. Thos. Anderson, H. Zedig, J. P. Martin, J. H. Dobinson and W. H. Hart were elected directors. E. B. Holmes was re-elected secretary, W. E. Shiron was elected superintendent in place of H. M. Gorham.

The following is Supt. Lyman's letter regarding the last week's workings of the Con. Va., which so many have read and re-read in an effort to determine something satisfactory—or the reverse:

"1650 level—From the top floor of south drift 1 on the sill floor of this level in the ore body recently found, an upraise has been carried up 6 feet, and this opening has been extended out to the end, a distance of 6 feet, all in ore of high grade, with signs of lower-grade ore in the top. South drift 1 has been extended 9 feet, the first 5 feet in ore which will average 550 per ton. The length of this drift is 35 feet, of which 31 are in ore; the face is in quartz, with some porphyry, carrying a low assay value. At the mouth of this drift an upraise has been carried up and connected with the south end of south drift 2, in ore of good quality. South drift 1 on the 1700 level has been opened and repaired to a point 112 feet distant south from the winze.

The ore extracted during the week amounted to 67 carloads—about 66 tons, the average assay value of which, per car samples, was \$95.42 per ton; the largest portion of this ore came from south drift 3, and the remainder from the opening above south drift 1. 1000 level—the Rule drift—From the upraise on the east side of the main drift, 585 feet south from the shaft station, at a point 95 feet up, a northwest drift has been advanced 38 feet, and from this drift, at a point 20 feet in, a west crosscut has been advanced 15 feet; face in porphyry. The west crosscut from the main drift, 370 feet south from the shaft station, has been advanced 50 feet; total length 95 feet. At a point 235 feet south from the shaft station an east crosscut from the main drift has been advanced 23 feet; face in porphyry carrying lines of quartz.

There has been an increase of several men in the working force of the Crown Point and Con. Cal. & Va.

During May \$69,000 was paid on the Comstock for labor in the mines—about 156,000 more than for April.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from L. V. Tuff in the Concordia mine, near Oranburg, Plumas County, to deposit tailings behind dams in Cogswell Ravine and Jackson Creek; from the Northern Placer Mining Company in their mine near Oranburg, Plumas County, to deposit tailings behind dams in Little Long Valley Creek; and from Thomas White in the Schuyler mine, near Igo, Shasta County, to deposit tailings behind dams in Dry Creek, give notice that a meeting will be held at Room No. 52, Flood Building, San Francisco, Cal., on June 26th, 1894, at 1:30 P. M.

For the South African Gold Fields!

THERE WILL BE DISPATCHED ABOUT JULY 1, 1894, Providing sufficient passengers offer, the superior, large and commodious iron steamer, SANTA CLARA, FOR CAPETOWN DIRECT.

Gold and Silver Miners and Mechanics preferred.

FIRST-CLASS PASSAGE TO CAPETOWN.....\$200
SECOND-CLASS PASSAGE TO CAPETOWN.....\$150

A large number having already engaged passage, early application to secure tickets is requisite. A competent Surgeon will be aboard. For information apply to

THE JOHNSON-LOCKE MER. CO.,
Passenger and Freight Agents, 204 Front St., San Francisco.
Or to WM. L. MERRY, Room 4, 204 Front St.

GOLD EXTRACTION EXTRAORDINARY!

Two Improved Crawford Mills have treated about one thousand tons ore at the Columbia Mine, Moore County, N. C., capacity of each mill being over 10 tons daily, and the cost of wear and tear 20 cents per ton. On a formal trial run of 100 tons, 84 per cent of ore's value was cleaned up in gold, exclusive of some rich concentrate produced by mill. Three additional Crawford Mills have been added to plant at this mine.

CHEAPEST AND BEST MILL IN THE MARKET.

MECHANICAL GOLD EXTRACTOR CO., 47 Broadway, New York.

W. O. ROSS, Sec'y and Treas.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled face for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

P. & B. PAINT.

Absolutely Acid and Alkali Proof.

FOR CHLORINATION WORKS, and Preserving Wood and Iron from Acid Attack, Rust or Decay.

P. & B. ROOFING.

Send for Circulars.

PARAFFINE PAINT CO.,
116 BATTERY STREET, SAN FRANCISCO.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-tightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, California.

The Johnston Concentrator.

SIMPLICITY OF CONSTRUCTION. GREAT DURABILITY. EASE OF OPERATION. INCREASED PERCENTAGE OF SULPHURETS SAVED.

THE JOHNSTON CONCENTRATOR.

(EXTRACT)
RISDON IRON WORKS.—The machine has the same monotonous record, i. e., they absolutely save all except traces of sulphurets. Ship Two more as soon as possible. Respectfully,
 (COPY)
THE RISDON IRON AND LOCOMOTIVE WORKS, San Francisco.
 GENTLEMEN: We have tested the Johnston Concentrator furnished us by you on trial; and after an exhaustive test, we are satisfied it is the best in the market. Please prepare and ship us—as soon as possible—THIRTEEN more machines.
 Yours truly,

Direct-Acting Electric Hoists.

The rapid hoisting of heavy loads from deep mines by the direct application of the power to the reel shaft without the intervention of gearing, offers favorable conditions for the use of the electric motor in hoisting work. Economy can be shown in the use of power, while a high hoisting speed can be attained. Gearing has its limits, both in speed and safety. On this page is illustrated a direct-acting electric hoist using flat wire rope, operated

by jaw type, that portion of the shaft upon which they slide being hexagonal in form. Both clutches and brakes are operated by cylinders using compressed air. A small air compressor driven by an electric motor is placed at the center of the hoist, supplying air for this purpose. The compressor is automatic in its action, stopping when the pressure in the receiver forming its base reaches a certain point, and operates entirely independent of the hoist. Two sets of valves, actuated by hand wheels, one for brake and one for clutch, are placed convenient to the operator on

made and access had to all parts. They are mounted on heavy bed plates, also used for the two hearings at each end of reel shaft. A rheostat of ample capacity is provided for obtaining the slower speeds, resistance being thrown in or cut out by means of a controller and lever for operating. A reversing switch and lever for lowering is also provided.

THE Spokane Miner and Electrician thinks a thorough treatise on gold milling and silver milling is a present

1000 H. P. DIRECT-ACTING ELECTRIC MINING HOIST, FOR FLAT WIRE ROPE.

by two M. P. type motors, one on each end of the reel shaft, each capable of developing 500 H. P., or having a combined output of 1000 H. P. This hoist is designed to raise a load of 10,000 pounds from a depth of 2500 feet in one minute. Of course, for hoisting or lowering men, or for other purposes, any desired speed can be obtained at the will of the operator. Lowering can be done under complete control of the motors and without the use of the brakes when desired. Post brakes of a very powerful and effective type are used, being drawn together by rods above and below the reel shaft, so that all parts move in parallel lines, distributing the wear equally on the brake shoes and applying the pressure at two points in each shoe equally distant from the center. The shoes are also pivoted at the center, so as to quickly adjust themselves to the faces of the brake wheels. The clutches are of the

each side of the center of hoist, each set controlling the brake and clutch on its side. A powerful means of operating both clutches and brakes is thus provided, requiring practically no exertion on the part of the engineer.

The brake wheels, reels, etc., are, as will be seen, of the usual form, the brake wheel being keyed to the hub of reel, which runs loose upon the shaft when not in clutch. The reel hubs are hushed with hard composition, means for their thorough lubrication and easy removal being provided.

Dial indicators operated by worm gears on reel hubs are attached to each reel, showing position of cage in shaft. All levers are arranged within easy reach of the operator, so that one man can attend to both reels and brakes without difficulty. Particular attention has been given to the motors, so that all adjustments can be quickly and easily

necessary addition to technical literature. If a demand exist for such a work in addition to current publications on that subject, probably the most valuable would be a compilation of the articles that have appeared in the past two or three years in this and other publications giving attention to such work.

RECENT TESTS of the locomotive Columbia, with seven-foot driving wheels in the Baltimore & Ohio Railroad, show spurts of two miles a minute. The B. & O.'s best record is thirty-three miles in thirty-five minutes, not quite so speedy as the New York Central—forty-eight miles in fifty minutes.

THE financial disturbance in the Argentine Republic has resulted in sending gold to 308. At this figure a paper dollar there is worth 32.46 cents in gold.

MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 381-382.

NEARLY five-sixths of the gold coined is in circulation; less than one-eighth of the standard dollars are in active circulation; about three-fourths of the smaller silver coin issue is in circulation. Recent treasury statistics show a falling off in the amount in circulation per capita. Estimating the population of the country at 63,275,000, the present per capita circulation would be \$24.54, a falling off of \$1.12 in four months.

Borax On This Coast.

This retention of the duty on borax is still an unsettled question. The borax deposits in this state and Nevada are valuable and their development depends largely upon congressional action. The industry represents about a million dollars a year. In '93 there were shipped over 7000 tons; the year before, 6500 tons. At present there are in operation about a dozen borax reduction works, at Lovelocks, Schmidt's, White Plains, Neuschander's, Columbus Marsh, State Line, Conn & Trudo's, Calm's, in Nevada; Daggett, Searles and Indian Wells, in California. The State Mining Bureau is in receipt of specimens from San Bernardino, indicating extensive and valuable borax deposits in that section.

To Be Practically Demonstrated.

The California Ground Electrical Company has incorporated to put the Emme Generator on the market. The inventor or originator of that process has for some time had his generator in operation to the entire satisfaction of himself and associates. The chief claim is that it is a constant electrical power with the minimum of expense, and without the use of the usual jars or boxes. The generator consists of forty-five plates, twenty-four of carbon and twenty-one of zinc, lying horizontally in three rows of fifteen each, with about one and one-half inches of space between them, all being connected by aluminum bands and bolts. The plates are each twelve inches square and five-eighths of an inch thick. On the generator dilute sulphuric and nitric acid is poured, with the alleged result of producing electric power far in excess of that of an ordinary cell battery of the same size, and at considerably less expense. Mr. Thos. Price, at whose works in this city the experiments have been made, calculates that during the ten days' trial there was consumed four and one-half pounds zinc, three and one-half pounds sulphuric acid, and twenty-two and one-half pounds nitric acid, developing an average of 2.23 amperes on motor, 25.86 amperes on short circuit, and 3.71 volts; the average fall of potential was .360; 98.73 watts were developed.

The inventor says the idea first occurred to him while engaged in metallurgical work in Georgia three years ago. He thinks that anyone possessed of sufficient electrical knowledge who will give the same amount of study to the subject that he has will arrive at the same conclusions.

"The Drain of Gold."

The movement of gold from this country to Europe is attracting universal attention. The reasons for it are as various as the reasoners themselves. But in stating a cause, what is new is not good and what is good is not new. It is one of the times when the wisest seem to be at fault. "All signs fall in a dry time," and the present is a very dry season. People who prophesied that the repeal of the "Sherman law" would stop the gold drain are as badly mistaken as those who thought the bond issue would mend the leak. When the Secretary of the Treasury declared that the drain was caused indirectly because of the purchase of silver bullion, Congress stopped such purchase; but the drain goes on, the noticeable thing about it being that all the remedies so far tried have proved ineffectual. In all the discussion, the logic of events is with the silver men; they have the best of the argument, for the declarations of the monometallists have all been negated by the inexorable facts.

On the first of this month the gold coin and gold bullion in the Bank of England amounted to over £36,000,000—the largest stock on record. Bullion went into the Bank of England during May as follows:

Date.	Amount.	Date.	Amount.
1.....	40,000 18.....	1.....	462,000
2.....	143,000 19.....	2.....	50,000
3.....	228,000 21.....	3.....	25,000
4.....	32,000 22.....	4.....	15,000
5.....	380,000 23.....	5.....	91,000
6.....	90,000 24.....	6.....	404,000
7.....	99,000 25.....	7.....	47,000
8.....	247,000 26.....	8.....	29,000
9.....	467,000 28.....	9.....	337,000
10.....	33,000 31.....	10.....	16,000
11.....	236,000.....		
12.....	140,000.....		
13.....	76,000.....		
14.....		Total.....	\$3,739,000

All this English plethora of gold does not come from the United States. In India, as elsewhere, the purchasing power of gold has appreciated, and the far East sends great sums in gold to London.

As a matter of fact, it would seem that the main reason for this great drain of gold is that its purchasing power since the demonetization of silver has so appreciated that it has become too valuable to hoard, and flows toward the financial center as the rivers flow toward the sea. It is within the limits of possibility that if gold continues to grow so plentiful in London, the English financiers, who are allowed by the supine policy of the United States to control the world, will seek to do with it what they have succeeded in doing with silver. It would be a gigantic sweep of the pendulum, but a not impossible one.

Returning to consideration of the present "drain of gold," it is interesting to observe the historic phase of the question. The following table is compiled from the most recent United States treasury reports. It represents the ebb and flow of gold to and from this country for twenty years; that is, ever since the demonetization of silver. It shows the excess of gold exports over gold imports, or of gold imports over gold exports, for each year:

Fiscal year ending June 30.	Gold movement—excess.	Fiscal year ending June 30.	Gold movement—excess.
1873.....	Ex. \$35,174,000	1884.....	Ex. \$18,929,000
1874.....	Ex. 14,840,000	1885.....	Im. 18,215,000
1875.....	Ex. 53,285,000	1886.....	Ex. 22,808,000
1876.....	Ex. 23,164,000	1887.....	Im. 33,209,000
1877.....	Ex. 344,000	1888.....	Im. 25,558,000
1878.....	Im. 4,125,000	1889.....	Ex. 49,697,000
1879.....	Im. 1,037,000	1890.....	Ex. 4,331,000
1880.....	Im. 77,119,000	1891.....	Ex. 67,139,000
1881.....	Im. 97,498,000	1892.....	Ex. 495,000
1882.....	Im. 1,798,000	1893.....	Ex. 87,508,000
1883.....	Im. 6,133,000		

The official estimate of the amount of gold in the United States on the 1st inst. is \$665,000,000, located in national banks as follows:

New York.....	\$35,707,000	Arizona.....	\$88,000
Illinois.....	26,000,000	Oklahoma.....	50,000
Pennsylvania.....	20,847,000	Montana.....	1,112,000
Massachusetts.....	11,650,000	Nebraska.....	2,123,000
California.....	7,700,000	South Carolina.....	103,000
Minnesota.....	4,116,000	North Dakota.....	229,000
Wisconsin.....	3,896,000	Connecticut.....	2,217,000
Indiana.....	3,800,000	New Hampshire.....	364,000
Missouri.....	3,340,000	Dist. of Columbia.....	1,230,000
Ohio.....	3,273,000	Indian Territory.....	38,000

Wyoming.....	226,000	North Carolina.....	294,000
Texas.....	1,122,000	West Virginia.....	385,000
New Mexico.....	100,000	Delaware.....	162,000

Treasury officials figure that the June exports will aggregate \$10,000,000.

"COMPULSORY ARBITRATION" is the title of a leading editorial in a leading Eastern trade contemporary, endorsing that method of settling labor difficulties. The terms are, however, contradictory. There can be no such thing as "compulsory" arbitration. As well talk of "dry" water or "heavy" hydrogen. The moment any process of arranging any dispute, labor or otherwise, becomes "compulsory," it ceases to be arbitration.

The secretary of the London Stock Exchange says that the total amount of foreign bonds held in Great Britain is \$3,820,000,000. The interest on the American portion of this enormous holding is payable in gold, forming a factor in the present eastward drain of the yellow metal.

American Consular Reports.

Some years ago the United States consuls at their several posts were required to furnish data relative to the manners, customs, manufactures, exports, imports, and general business statistics. The duty became a permanent one; hence the State Department and later on the public press are constantly furnished with a vast amount of information, more or less valuable.

While much of this is good, there is, necessarily, a large percentage of doubtful value, for, however clever or deserving our consular service may be, its individual members must take much from hearsay. Information to be valuable must be accurate.

Mr. Benedict, U. S. Consul at Capetown, reports upon the gold yield of South Africa. He figures that the total for '94 will be 2,400,000 ounces. That is considerable, but bigger figures follow. Estimates are furnished of the "Rand" tract, showing that deep mining should, could or would produce a gold yield of \$1,710,596,000. These figures are applied to a small part—about one-fourth of the district. There are about a dozen districts, and the millions pile up, in Mr. Benedict's belief, till California is "not in it." While one's soul rejoices in the mere contemplation of such auriferous possibilities, still, examples of mining prophecies nearer home exemplify how widely such estimates may go of the truth. It is not given to every one to be a Philip Didesheimer.

Mr. Mason, U. S. Consul at Frankfurt, Germany, writes regarding a new process of making steel castings from iron or steel, by means of electricity, the castings to be warranted free from blowholes, which should be of interest to Messrs. Carnegie, Herbert, et al. The Tausig process is the name given to the method. The smelting and casting are done by electric heat influenced by rarefied air. The fused metal flows by gravity from the furnace to the moulds, and it is claimed that the work is successful, the electric current obviating the ordinary trouble arising from impurities where coal or other fuel is used.

The theory is a pretty one, and were heat alone required the facts might be made to fit. Heat being merely secondary, the entire metallurgical process of reduction from ore to iron or steel being a complicated one, it would appear that the whole thing is another case of where the facts run at right angles to private opinion. Then, again, it is figured by Mr. Mason that the cost of the electrical power is but trifling. But Mr. Monaghan, another United States Consul, at Chemnitz, Switzerland, makes another report, showing that the cost of production of electrical power in that class of country represented in Mr. Mason's conclusions is at least as much if not more than that of equivalent horse-power produced by steam.

While in these cases the standard of criticism must not be an exacting one, yet it would appear that in some of these reports the value to the reader lies largely in knowing what to reject, and in discounting many of the confident assertions.

To Relieve Mining Men.

The effort to induce Congress to re-enact the mining assessment law of '93, postponing the assessment work on mineral claims for the current year, ought to succeed. The claim made by those opposed to it, that it puts the miner in the attitude of a mendicant, is of no moment. It is a question of business, not sentiment. Of course, it isn't what would ordinarily be asked or expected, but in the present stress it is in order for a miner to ask an extension of time just as an embarrassed business man would wish a time of grace to meet his obligations.

The following is illustrative of the general feeling in regard to the matter. It is a report of a meeting held in Spokane, Wash., on the 1st inst.:

Another meeting of the mining men was held at L. K. Armstrong's room in Temple Court last evening, and after the minutes of the previous meeting had been read and adopted the committee on resolutions reported the following memorial, which was unanimously adopted:

To the Hon. Watson C. Squire at United States Senate Chambers at Washington, D. C., and to the Hon. John L. Wilson and W. H. Doolittle at the House of Representatives, Washington, D. C.: Your memorialists, citizens of the state of Washington, respectfully represent that we are largely interested in mines and mining properties; that we have contributed in a great degree to the development of said properties; that few of the properties we are interested in are upon a paying basis, and that their value is almost entirely a prospective one; that we have kept up the annual assessment on said properties hoping to interest capital to the full development of the same, and in view of the present depressed condition, financially, of the country we find it an impossibility to interest capital or to raise the necessary funds to do the assessment work; therefore, if the relief asked for is not given we will lose our investments and valuable property.

We, therefore, respectfully solicit that section No. 2324 of the revised statutes of the United States relating to mining claims be amended by suspending for the year 1894 the performance of \$100 worth of work as required by said section No. 2324, and that the provision of an act entitled "An act to amend section 2324 of the revised statutes of the United States relating to mining claims," approved November 3, 1893, be extended for a period of one year, so as to cover and embrace the year 1894.

Concentrates.

The Utica mine yielded \$225,000 in May.

PLACER COUNTY will have its day at the Midwinter Fair next Saturday.

WORK is to be resumed this week in the Grizzly Ridge mine, near Columbia Hill.

SAN FRANCISCO attorneys have attached the Suro tunnel for alleged legal services.

The Great Western Quicksilver Mining Co. is putting in new and improved machinery.

The new 40-stamp mill at the Madison mine runs like clock-work, says the Angels Echo.

The Red Roy mine on Clear creek, Baker county, Or., has sent a \$2500 cleanup into Baker.

The Rose Hill Gold Mining Co., is a recent Oakland, Cal., incorporation; capital stock, \$100,000.

The Hidden Treasure mine, Placer county, is about to incorporate with a \$350,000 capital stock.

The Buchanan Gold Mining Company of Tuolumne county has been assessed 12½ cents per share.

The Helvetia Mill and Mining Company has incorporated at Los Angeles, Cal., with \$100,000 capital.

With a capital stock named at \$12,000,000 the El Coronado Mining Co. has incorporated in this city.

The Morning Star Mining Company of Iowa Hill, Nevada Co., has declared a dividend of \$3 per share.

A ROASTER is being erected to refine the black quartz of the Little Anaconda mine at Wolf Creek, Oregon.

A 400-POUND nugget of solid copper is reported found in the bed of Rainy river, thirty miles from Sheboygan, Mich.

The Stanley Mining Company was incorporated in this city last Wednesday. Capital stock, \$100,000, all subscribed.

The Ward mine, at Whitlock, Mariposa county, will be operated by electric power furnished from the Merced river.

THIRTY men are now employed at the Gwin mine. The hoisting works will have a sinking capacity of 3000 feet.

The New Golden Rule Mining Co. is building a ten-stamp mill on the Middle Fork of the American river at Horseshoe Bar.

A GOLD STRIKE is reported from Dutch Tom Gulch, near Lander, Wyoming. Some of the dirt is reported as high as \$25 to the pan.

The Reno Borax Company has been organized to work the borax fields at Grant and Sulphur Springs, 100 miles north of Reno, Nev.

WHITE labor is not in demand at the British Guiana, South America, gold mines. The ruling rate of wages is fifty-four cents a day.

ONE HUNDRED men have been sent to Monte Cristo to begin work on the mines there, and the plant will go ahead full blast twenty-four hours a day.

GOLD DISCOVERIES are reported at Deer park, five miles north of Nevada City, made by T. P. Frances, who is said to have located several new ledges.

The Bradley Mill and Mining Company was incorporated in this city last Tuesday. Capital stock \$1,000,000, of which \$25,000 has been subscribed.

The United States manufactures more iron, steel, copper and lead than any other country on the globe, Great Britain being a little ahead on zinc and tin.

The owners of the Last Chance claim, Big Bend, have spent \$22,000 piercing 2200 feet of tunnel in all, and have not struck bedrock. Work will continue, however.

BOA INCAESOL believes in silver, but not in God, which inspires the reflection on the part of the Tombstone Epitaph that Bob has a Christian spirit, even if he is an infidel.

The "great gold find" reported on Box creek, Montana, turns out to be a fake. There was some fine gold found in the grass roots, but there is nothing to speak of below.

The quartz mill at Hiko, Nev., was entirely destroyed by accidental fire last week. The mill had been crushing ore from Ferguson district. The Eastern owners will rebuild.

IN THE business office of the MINING AND SCIENTIFIC PRESS this week a subscriber paid for his paper renewing from date of expiration to the close of the century—Dec. 31, 1900.

THE Great Vulture mine in Maricopa county, Arizona, which is credited with a production of \$15,000,000 in gold, is to be reopened. It is the property of ex-Senator Tabor of Denver.

FROM San Diego come reports that new placer diggings of considerable extent and richness have been found four miles from the camp of Juarez, below the boundary line, near Campo.

THE Tyler and Last Chance mines in the Coeur d'Alene have tired of litigation and contest for the same piece of ground and have consolidated in one company, to be worked as one mine.

SENATOR POWELL of Montana has gone a little beyond any previous effort in that direction, by introducing a bill suspending all annual assessment work for three years—'94, '95 and '96.

WILLIAM O'BRIEN writes to his Spokane friends that he has found diggings on the Clearwater, about seventy miles from Grangeville, which will yield from \$10 to \$15 per day with rockers.

THE current statement that "Cochiti, New Mexico, is a poor man's camp" causes the *Prospector* to enter the comment that this may be said with emphasis about all silver-mining camps just at present.

THE general manager of the Santa Fe railway system says that the traffic from the mines of New Mexico and Arizona brought more money to his road last year than the grain fields of Kansas and Oklahoma.

THE Nevada City Transcript learns that a French syndicate has been formed with a very large capital stock, and is now negotiating for the purchase of the Watt and other gravel mines in Bloomfield township.

ACCORDING to the Tombstone Epitaph, the Santa Fe railroad

company owns the biggest fire insurance policy ever written. It is for \$17,000,000 and covers every piece of combustible property that belongs to the company.

THE Bunker Hill and Sullivan mines, at Wardner, Idaho, have closed down, because the railroads are flooded and cannot handle the ore. Work is to be resumed as soon as the roads are ready for business.

MESSESS. HARVEY AND KITTO of Jackson, who won the first prize at the Midwinter Fair drilling contest, have accepted a challenge from two Angels Camp miners to drill against them for a prize of several hundred dollars.

THE first shipment of ore from the new development on the 1650 level of the Consolidated California & Virginia mine was made to the Morgan mill last Sunday. It included 160 tons of bulk assays, showing an average value of above \$90 per ton.

WALTER LASSWELL, employed in running the concentrators at the Rawhide mine, near Sonora, Tuolumne Co., for some months, has been arrested charged with stealing amalgam. Twenty-five pounds of amalgam were found in a tin can in his trunk.

A CANDLE-BOX of very rich specimen ore, literally filled with gold, has been brought to Nevada City, says the *Union*, from Kanaka creek in Sierra county. The find is regarded as a big strike. The name of the mine from which the rock came is the Tessler & Leon.

ACTIVE operations will shortly begin at the Centennial mine about fifteen miles from Nevada City. The ground incloses about one thousand acres, under which runs the old blue gravel lead. The main gravel channel has been developed by a 2600-foot tunnel, and rich results are expected.

AT LAST Wednesday's meeting of the Debris Commission a number of applications were received, but none were granted. Col. Benyard and Major Huer left last Thursday to inspect some hydraulic claims in Plumas county, the owners of which have made application to the Commission for permits to operate.

TWO Spokane men recently located 530 acres of placer ground in Grant county, Oregon, tests of which yielded fifty cents to the yard. They have made arrangements with Seattle men to spend \$50,000 in putting in a plant, and soon expect to have a dredge hauling from 1500 to 2000 cubic yards of gravel per day.

THE operators of the Cripple Creek mines cite that the wages they paid were as high as those paid at Leadville. The *Georgetown Courier* claims that the miners have to pay from two to three prices for everything they buy of Cripple Creek merchants. The cost of living there is said to be twice what it is in Leadville.

THE BUTTE *Inter-Mountain* says the most important happening of the week was the starting up of Anaconda's mammoth upper works smelter, which has been idle a long time. The Montana Ore Purchasing Company is adding improvements to its smelting and reduction plant that will cost, when completed, \$50,000.

DURING the past six months many new and valuable gold discoveries have been made in Nevada, and the *Enterprise* thinks that the opportunities for success in gold mining in Nevada are to-day far better than they are in South Africa. There the poor man has some show as well as the capitalist who enters the field with unbounded means.

THE *Union* reports that the Mountain Chief mine, at Willow Valley, has been bonded to Orlando Stoddard of Grass Valley by Messrs. Locklin, Dean and Ragon of Nevada City. A new two-compartment perpendicular shaft will be sunk to a depth of 100 feet, suitable machinery for the working of which is now being placed on the mine. It is a good prospect.

BY an agreement between the creditors and the owners, the Gover mine, near Amador, has been leased to a committee of five representing the former, in whose interest the mine will be run. The output of the mine under the lease is to be used to pay the labor employed by the new committee and the surplus to liquidate the claims of the holders of time checks, etc.

THE *Democratic Banner* of Sonora, Cal., says that a company composed of Chinese, with Chew Knn at the head, has taken charge of the Manzanito mine on the Stanislaus river, owned by Otto Kanig. A five-stamp mill has been purchased and is now on its way to the mine. This is believed to be the first company of Chinamen that has ventured into quartz mining in this State.

THE Shakespeare mill, near Forbestown, Butte county, which has been idle since January 1st, has started up again. Ever since the mill was shut down, development work has been carried on and the bins are full of ore and there is a good supply of rock in sight. At present, says the *New Era*, only ten stamps will be used, but the others can be started at any time, should it be found advisable to do so.

J. F. CLEMENT has sued Charles L. Hall in the Arizona District Court for possession of one-eighth of the Mammoth mine in Superstition district, forty miles east of Phoenix, and for \$25,000, estimated to be the share of net profits due on the one-eighth for the past year's operations. Clement is a mining expert on whose report Hall bought and alleges that the property is worth a quarter of a million.

RACANT mining companies incorporated at Denver, Col., are: The Great Western Gold Mining and Milling Company, capital stock \$700,000, Denver; Altrou Mining Company, capital stock \$200,000, principal office, Creede; Ramona Gold Mining and Milling Company, capital stock \$100,000, Denver; Duquesne Mining and Milling Company, capital stock \$1,000,000, principal office, Pitkin; Western Mining and Development Company, capital stock \$100,000, principal office, Jersey City, N. J.; principal Colorado office, Aspen.

HENRY HANSON, an old California miner, has been over at Westport, Wash., looking at General Don Carlos Buell's plant he has put up at Westport to extract gold from the sands of the ocean beach. He tells the *South Bend Journal* that when he arrived there General Buell was preparing to leave. The experiment has proved, it seems, a failure. Hanson panned out some of the sand. He found only a few colors, and they were small flakes as fine as gold leaf. Thus again have gold beach hopes vanished into thin air.

REPORT comes that the San Juan placers in southeastern Utah have been abandoned. Machinery was put in at a considerable

expense, but failed to extract the gold. There is gold in paying quantities in the placers, but it is almost as fine as flour and will have to be put through a process of amalgamation before it can be saved. The gold, unlike most placers, is in a cement formation that is almost impervious to water, and the ordinary methods of washing and sluicing will not dissolve the cement. These placers will have to be worked in a similar manner to gold-bearing rock, by mill process, before the fine gold can ever be successfully extracted from the cement.

A LETTER from the southern part of Lincoln county, Nevada, informs the *Record* that all the miners at the Keystone mine are under arrest for stealing ore. It is stated that for some time past the company suspected that small quantities of the richest ore were being systematically got away with. A detective was employed and put to work with those in the mine engaged in the stealing. The day shift would steal the ore and cache it, and the night shift would secret it under a mesquite bush. The work had been going on for some time, two wagon loads being shipped and preparations were under way for a third shipment when the matter was brought to light. An effort was made to place all the miners under arrest but three succeeded in escaping.

Clipped and Condensed.

GRANT, Sherman county, Oregon, has been destroyed by a flood.

A MILLION-DOLLAR FIRE swept the city of Panama last Wednesday.

A \$75,000 FIRE destroyed a part of Globe, Arizona, last Saturday.

THE Midwinter Fair Executive Committee announces the Exposition will close July 4th.

THIRTY THOUSAND MINERS on the island of Sicily are starving and hopeless of an improvement.

It is thought probable that the Pacific Railroad Funding bill will be defeated in the House Committee room.

THE Columbia and Fraser river floods are subsiding. The damage is estimated in millions, and loss of life is reported.

THE Dowell Observatory at Flagstaff claims to have discovered two star-like lights within the south polar snow cap of Mars.

UNLESS an envelope states the number of days a letter is to be held, the postmaster, by a new ruling, will hold it 30 days instead of ten.

STAKING coal miners in Ohio, Pennsylvania, Illinois and Alabama have inaugurated a dynamite campaign, destroying bridges and terrorizing wherever possible.

DESPITE Gov. Waite and other meddlesome politicians, the Cripple Creek, Col., mining troubles are almost ended. Arbitration has resulted in the miners carrying their point on the wages question.

THE deadly black plague is devastating the Chinese coast, 60,000 are reported to have died, half of Hongkong's population has fled, and fears are expressed that the disease will spread to other countries.

SUITS for \$15,000,000 each against the Crocker and Hopkins estates will shortly be instituted by the United States for the recovery of the debts owed by them to the Government as stockholders in the Central Pacific Railroad Company.

THE Illinois Supreme Court has decided that citizens of the United States cannot acquire title to real estate by inheritance when the inheritance has to be traced through alien ancestry, alleging that such alien ancestry is without inheritable blood, which is necessary to transmit an inheritance from one person to another.

THE House Committee on Commerce will shortly submit a favorable report on Senator Morgan's Nicaragua Canal bill, with some modifications. Seventy millions of stock is to go to the United States, \$1,500,000 to Costa Rica and \$6,000,000 to Nicaragua, as provided in the original bill. The Maritime Canal Company is to receive \$4,000,000 of stock as compensation for their expenses.

THE English combination of coal-mine owners has decided to make a general reduction of ten per cent in wages. The miners are organizing to resist the reduction. A cablegram from Edinburgh says that the Scotch Mine-Owners' Association has been officially notified that 7000 men would strike on June 24th if the association persisted in carrying out its intention of reducing wages one shilling a day.

LAST Tuesday, Senator Squire of Washington introduced a bill for the coinage of silver. It provides that the owner of silver bullion may deposit it at the Mint, receiving in payment standard silver dollars equal to the value of the bullion on the day of deposit, the difference to be retained by the Government as seigniorage and to be used as a reserve fund by the Secretary of the Treasury in maintaining the parity of silver dollars. The coinage of silver dollars shall not exceed \$4,000,000 each month. When the aggregate amount of money in the country reaches \$40 per capita, further silver coinage shall be discontinued and shall be resumed when it falls below that figure. Provision is made for coining silver half dollars of the present size and maintaining their parity in the same manner as other silver. They are also made legal tender.

Personal.

CONGRESSMAN CAMINETTI is visiting friends in Jackson, Amador Co.

E. B. PRATON, of the State Mining Bureau, is collecting data in Plumas Co.

SUPERINTENDANT L. L. MYERS has taken charge of the North Bloomfield mine.

GEO. MAINHART, of Grass Valley, is going to start up his Dublin Bay mine in a few days.

JOHN D. GOSSE, of Spokane, Wash., is to have charge of the German mine, near Washington, Nevada Co., which will shortly start up work again.

THOS. B. EVANS, a wealthy Colorado mine owner, has returned to Denver. During his recent visit here he bought a large placer plant, costing several thousand dollars, from The Risdon Iron and Locomotive Works. It is now being shipped to Mr. Everett's mine at Cripple Creek.

A Disastrous Rush from Coolgardie.

A prospector came in and reported having discovered payable gold 65 miles northwest of Coolgardie. It soon became known that Ernst (this was the prospector's name) had applied for a reward claim. The 80 ounces he had brought in were soon magnified into several hundred ounces, and the greatest excitement prevailed. Men could be seen pouring into Coolgardie from all directions, many groaning under their loads of tents, tools and worldly possessions, and all eager to get the first dray bound for the rush. Every vehicle and horse to be had was pressed into the service, and the storekeepers were rushed with diggers procuring supplies for the field.

Before nightfall fully three-quarters of the tents had disappeared, and their occupants were on their way to the rush. By some unaccountable blunder the teams all started out southwest instead of northwest.

They got to the Raeside soak, 35 miles from Coolgardie, all right, and were of opinion that they were within 30 miles of the find, instead of which they were farther off it than when they started from Coolgardie.

Their troubles then commenced. The country between the Raeside water and the rush is a sandy, waterless desert, trackless and destitute of landmarks to guide the traveler who might miss his way. Most of the teams, loaded with diggers' swags, tools and provisions, made the Raeside soak the first night, filled their tanks with water, and set off in a westerly direction, expecting to make the rush by night or early next day. Instead of making 20 or 30 miles, as they expected to do, they found the sand so deep and heavy that they could only do five to eight miles a day. They could only travel two or three days at this rate, and their water having run out, they would then throw off their load of swags, etc., and return to the water to fill up their tanks again. Some of the diggers would fill up their water bags and camp until the drays returned. Many of them, however, in their eager desire to reach the rush and be early on the field, started to walk. As they were all going west instead of east, they were always getting farther away from the rush, and as many of them, so soon as they thought they had traveled far enough to be on the field, struck out in a new direction, there were scores of men wandering about hopelessly lost, with empty water bags, on a sandy desert, with a fierce sun glaring on them all day. Walter Besant came into Coolgardie just a week after the rush was reported. He was delirious and wild from thirst, exhaustion and anxiety. But he was able to make known that a terrible disaster had happened. The authorities of the water supply acted with great promptness, dispatching camels loaded with water in a southwest direction to pick up and succor the lost ones, and sending horse wagons with tanks of water northwest to supply water to those who, having reached the field and found it a failure, would be returning by this, the right track, to Frost's rush or the 65-mile. What with camels in one direction and water carts in another, the water-supply people established a circle of water, saving the lives of some, and reducing the sufferings of many. Owing to the hardships and sufferings by the way of those who attempted Frost's rush, it acquired the name of Siberia, by which it is now known.

It is, however, believed that some of the lost ones never returned.—Australian Mining Standard, April 21st.

A Slightly Damaged Armor Plate.

Irving M. Scott of the Union Iron Works is authority for the statement that there is a slightly damaged armor plate on the United States coast defense vessel Monterey—one and no more. Further, he says, the Carogies knew about it, and the Government inspectors knew about it, and the latter accepted it with a full knowledge. He adds that the defect is not one that, in the opinion of the inspectors, affects its shotproof quality in any degree.

"The acceptance of the plate came about in this way," said Mr. Scott last evening. "The Monterey had been fully armored, save for one plate, and there was supposed to be need of her quick equipment because of the trouble with Chile. When this plate was inspected it was found that it carried on its end a slightly crystalline formation that was recognized as of slight importance, and it was decided to accept it, pending the casting of a new plate.

"The plate was sent out and put in place. Before work was begun on the new plate the Government decided, in consideration of a cut in the price, to accept the old one for the permanent armor, because, as stated, the defect was immaterial.

"All this talk about defective armor plates for the navy is simply nonsense," continued Mr. Scott, "and the greatest harm it does is in creating prejudice with the Senators and Congressmen from Inland States, who have little fear of foreign invasion and are quick to find reasons for refusing to vote appropriations for the navy. The fact is, as

Mr. Herbert himself says, the armor plates have been shown to be 5 per cent better than the specifications.

"There has been no secret about this defective plate, and the only reason I have not spoken of it before was that I was not asked."—San Francisco Call, June 9.

Simple Enough.

As a change from the story of Columbus and the egg, which may now very properly be laid aside until 1992 draws near, an incident related by a French man of science and vouched for by him may be told. This gentleman relates that he was at work before a glowing coal fire when some one tapped at the door, and a young girl belonging to a family who lived in a flat above him came in.

"Sir," she said, "would you kindly lend me a live coal or two to start our fire with? It's gone out."

"Certainly, my dear," said the savant. "But you have brought nothing to carry it in. Take my shovel."

"Oh, no, sir," answered the child. "I will carry the coals in my hands."

"In your hands? What do you mean? You'll be burned."

"Oh, no, sir. I'll show you how."

The child dipped up some ashes from the grate and placed them in the hollowed palm of her left hand. Then, with the tongs, she laid two burning coals on the top of the little heap of ashes. Then she bowed, smiled and went out, bearing her coals unharmed.

"Well, well!" said the man of science to himself. "Here I've been studying natural philosophy 40 years and never had the wit to do that!"—Youth's Companion.

Will Try It Again.

A party has been organized on the Klamath River to again institute a search for the wrecked Brother Jonathan. The history of the disastrous wreck and story of the immense treasure known to have been lost with the steamer are widely and familiarly known, and from the time of the sad event, some thirty years past, there have been repeated efforts made to locate the wreck and oftentimes its recovery reported. The company now having in contemplation its recovery will have its investigation probably based upon more reliable information than some previous efforts. The magnetic indicator with which they are provided is a new departure, the invention of Silas White, who was an original projector of the enterprise. The instrument consists of an arrangement similar to a surveyor's compass, the needle, however, being suspended so as to work perpendicularly, and to indicate the presence of iron. The immense amount of iron with which the vessel is known to have been freighted makes the project entirely feasible, as the needle is warranted to work satisfactorily to a depth of twenty or more fathoms. Some of the company are now stationed on the shore opposite the scene of the proposed researches.

That's the Way It Is, Sometimes.

In the history of prospects there is something peculiar. The first locators seldom, if ever, realize anything from the find, save hard knocks and privations. Lean streaks are encountered and the properties in many instances are abandoned, grass grows over the dumps, and the shafts or tunnels, as the case may be, come together. Years afterward other prospectors relocate the claim, go to work and find the mine just a few feet from where their predecessors left off working. Many an old weather-beaten prospector, who has toiled and borne the brunt of privation and at times of nearly starvation, has lived to realize that the claim he so patiently worked for months and perhaps years, and finally abandoned through discouragement and the pinching out of grub resources, is now panning out thousands upon thousands to the company to whom it was sold by the second locator. Philosophically, however, he chews the "cud" and keeps the heads of his drills well polished in quest of wealth in some other lead.—Silverton Gazette.

Corner in the Diamond Market.

Of the diamond market the *Jewelers' Circular* says: "Less than three months ago the entire stock of the company controlling the output of the world was sold to a London syndicate for \$6,250,000, the price per carat being in advance of that paid at a large sale just previous to that time. The stock of the company then advanced several per cent and the advance is still maintained. It is also untrue that shrewd buyers can now obtain small stones at a bargain in the European markets. The market was stripped of well-cut stones by the American buyers last year, and the tendency of prices is now upward, the fine goods being bought up by Europeans as rapidly as the cutters can turn them out. There is no immediate prospect of a decline from present prices."

Stagnation in Cariboo.

The following summing up of the outlook for Cariboo is contained in a private letter to the Kamloops *Sentinel*. The letter is dated Barkerville, April 20. It says: "At present the outlook is very blue. The place has grown from bad to worse ever since you left. As far as a man looking for work goes, it is almost out of the question, as no drifting claims of any account are at work now. The principal mining is hydraulic, and very little of that. There are more men here now than get employment, but rumor has it that we are to have a boom in the near future. A. D. Whittier has a lease of all the vacant ground on Williams creek, and the ground held as real estate he has bonded. He proposes to work the creek from top to bottom by a machine called an hydraulic jet. Slough creek is also held by a company of Americans. They are just about ready to try and sink their shaft. Law, late commissioner at the world's fair, has a scheme on foot to prospect Willow river below Mosquito creek. He is going to bore with some kind of an auger and has the old Lowhee engine on the ground. J. Allen and Frank Petries think they have found a continuation of the old Heron lead on Grouse creek. They ran a tunnel below where the pay streak was lost and sunk a blind shaft. They got six ounces out of the shaft. Quite a number of ten-mile leases have been applied for on Willow, Goat and Smoky, as well as on the Fraser. There are no new strikes. Hobson, at the forks of the Quesnelle, is going into hydraulic mining extensively, but he only pays about \$40 a month and board. George Isaac and Arthur Johnston and another man are on Stuart's creek prospecting. Arnold Wilson is working for Flynn on Mosquito creek. John Wilson is back on Lightning creek prospecting on the bench opposite the Costello. Barkerville is almost deserted; about twenty in the town now, all told."

They Own Gold Farms.

W. P. Russell has returned from a visit to his new placer property at Crane's flats in the Granite mining district, tributary to Baker City. He says he found the country much better than he expected, and states that the people of Baker City are now making arrangements to build a smelter and handle their ore at home.

"We have made a contract with a syndicate to put in machinery and work our property," said Mr. Russell. "They will put in a two and one-half mile flume, the whole dredge, steam pumps, elevated sluice boxes, etc., the whole plant costing from \$30,000 to \$50,000. They will begin building at once and expect to have the machinery at work within two months. It will run day and night, handle from 1000 to 3000 cubic yards per day. We have 580 acres of ground, yielding from 75 cents to \$1.50 in gold per cubic yard.

"This district has been worked constantly for thirty years, yet last year the banks at Baker City took in \$1,000,000 in gold dust and a great deal was shipped directly to the mints and assay offices. The country was first filled by old forty-niners from California, who realized that they had found a good field and stayed with it. Some of them are still there and have their children and grandchildren around them. Placer mining is regarded much as farming is in other places where the crop is sure. Everybody has money, too. But new capital is coming in now and the condition of the country is changing rapidly."—Spokane Chronicle.

Victory for Price.

Judge Morrow of the United States District Court awarded Thomas Price a judgment in the sum of \$70,000 against the owner of the British ship Elmbank, for saving the vessel and her cargo from destruction by fire. It will be remembered that the cargo of sulphur in the hold of the Elmbank became ignited while the vessel was at the dock in this port, and for several days efforts were made without success to extinguish the flames. Finally Professor Price was called upon for assistance. In about two days' time he succeeded in putting out the fire by the use of chemicals. The value of the vessel is \$76,000 and the cargo of sulphur was worth \$21,000.

Obituary.

Captain E. B. Zabriskie, the outgoing melter and refiner of the Carson mint, died suddenly of heart disease last Sunday.

Ex-Governor Rodman M. Price of New Jersey died at Oakland, N. J., on the 7th inst. He was a participant in the raising of the American flag by Commodore G. G. Sloat at Monterey, Cal., July 7, 1846, and a member of the constitutional convention at Monterey, Cal., in September, 1849; was formerly an officer in the United States navy, and when the American flag was raised in this region he was the first to exercise judicial functions under it as an alcalde.

THE UNION DEPOT.

THE W, ON THE ROAD FROM PIKE'S PEAK TO THE VALLEY.

SIGNAL STATION ON THE TOP OF PIKE'S PEAK.

A VIEW ON THE RIO GRANDE SOUTHERN IN EARLY SUMMER.

COUNTY COURT HOUSE, DENVER.

In and Around Denver, Col.

Second only to California in the beauty and extent of its scenery is the mountain State of Colorado, and second only to our own Pacific coast cities in much that makes manifest the march of progress is the pleasant city of Denver, where meet so many diverse elements, and where on every hand is such tangible evidence of wealth.

'Twas said of a famous wit and raconteur, that so great was his flow of animal spirits, so infectious was his immediate personality in promoting fun that one had to drink to keep sober in his company. Kindred exhilaration is experienced by the sojourner in Colorado's capital. The "Queen City of the Plains," with its 175,000 people, whether seen in the gold and gray of the morning, the full splendor of a cloudless noon, or the blue and silver of the night, is a splendid spectacle, an inspiring sight.

It has been our pleasure and our privilege to visit that pleasant city and other Colorado industrial centers more than once, and have found the people fully awake to their advantages, and determined to make all their past achievements but an index of what they propose to accomplish in the future.

Though sharing with the rest of the country in the present depression, the resources of Colorado are of so valuable and permanent a nature as to insure a quick return of the prosperity so manifestly due. Like our own great State, Colorado takes the precious metal from the ground, thus adding to the permanent, indestructible wealth of the world. The Centennial Commonwealth has thus augmented the general wealth hundreds of millions of dollars. Mining is the backbone of Colorado's prosperity, though it must be borne in mind that her manufactures represent over \$100,000,000 annually, and her fields and stock ranges \$100,000,000 more. We of California have so much scenery of superlative grandeur that even the superb landscapes and mountain views of Colorado fall to make much of an impression on a Californian, but we herewith present a few illustrations of Denver and vicinity, thus portraying the works of man rather than those of nature. Colorado's excellent system of railroads enables the visitor to quickly and easily see the principal points of interest in the State, and much that is worthy the chronicle of pen and pencil may be found in even the briefest passage through its limits.

The League of American Wheelmen will hold their mid-summer meet in Denver this year in the interest of good roads and kindred topics, and that city is now making preparations to receive and welcome its visitors. Acknowledgement is due Mr. Edward B. Light, secretary of the Denver Chamber of Commerce, and Mr. Sterling Elliott, editor of *Good Roads*, for courtesies extended, including the views that accompany this brief reference to one of the most attractive sections of the country.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894 by Henry G. Hanks, F. G. S.

Maltha is a Latin word derived from the Greek. The ancients made a distinction between petroleum and asphaltum; they sometimes confounded maltha, which partakes of the nature of both, with asphaltum, but their descriptions show that they were familiar with liquid bitumen or maltha.

Herodotus (Melpomene 195): "Near them, the Carthaginians say, lies an island called Cyraunis, 200 stades in length, inconsiderable in width, of easy access from the continent, and abounding in olive trees and vines. They add that in it is a lake from the mud of which the virgins of the country draw up gold dust by means of feathers daubed with pitch. Whether this is done I know not, but I write what is related; it may be so, however, for I have myself seen pitch drawn out of a lake and from water in Zacynthus, and there are several lakes there. The largest is 70 feet every way and two orgyæ in depth. Into this they let down a pole with a myrtle branch fastened to the end; it has the smell of asphalt, but is in other respects better than the pitch of Pieria. They pour it into a cistern dug near the lake, and when they have collected a sufficient quantity they pour it off from the cistern into jars."

Strabo (Book 16, chap. II-XLIV): "Near Moasada are to be seen rugged rocks, bearing marks of fire, fissured in many places, a soil like ashes, pitch falling in drops from the rocks."

Vitruvius (Architecture, Book 1, chap. V): "I do not think it requisite to dilate on the materials whereof the wall should be composed, because those which are most desirable cannot, from the situation of the place, be always procured. We must therefore use what are found on the spot, such as square stones, flint rubble stones, burned and unburned bricks; for every place is not provided, as is Babylon, with such a substitute for lime and sand as burned brick and liquid bitumen."

Pliny (Book 2, chap. CVIII): "In Samosata, a city of Commagene, there is a pool which discharges an inflammable mud called 'maltha.' It adheres to every solid body which it touches, and, moreover, when touched it follows you if you attempt to escape from it. By means of it the people defended their wall against Lucullus, and the soldiers were burned in their armor. It is even set on fire by water. We learn by experience that it can be extinguished only by earth."

Ovid, in his story of Byblis, refers to maltha as he knew it. "Immediately, as drops from the cut bark of the pine tree, or as the viscid bitumen flows from the impregnated ground, or as water, * * * etc." (Met. 9-658.)

The ancients were aware of the nature of petroleum and to a limited extent made use of it, but they never explored for it by sinking deep wells as the moderns do. A number of ancient writers refer to it in their works.

Strabo in his geography (Book 5, chap. IV) 8 states the following: "The land about Vesuvius contains fat and a soil which has been subjected to fire, and is very strong and productive of fruit. When this fat superabounds it is apt, like all sulphurous substances, to take fire; but, being dried up by evaporation and pulverized, it becomes a productive earth."

Vitruvius (Architecture, Book 8, chap. III): "In many other places the springs, rivers and lakes which are near salt pits are therefrom rendered salt; others running over veins of fat earth issue forth impregnated with oil, as at Solæ, a city of Cilicia, a river called Liparis, in which those that wash or swim are, as it were, anointed by the water. In Ethiopia there is a lake which anoints those that swim therein. In India there is another which, when the sky is clear, emits a great quantity of oil."

Pliny (Natural History, Book 35, chap. LI): "There is also found an unctuous liquid bitumen resembling oil in a spring at Agrigentum, in Sicily, the waters of which are tainted by it. The inhabitants of the spot collect it on panicles of reeds, to which it very readily adheres, and make use of it for burning in lamps as a substitute for oil, and also for the cure of itch-scab in beasts of burden." Quoting from Polycritus, the same author continues (book 31, Chap. XIV): "The water of the river Liparis, near Soli, in Cilicia, is used as a substitute for oil."

Diodorus Siculus (Supplement to Book 17-5): "At the time he was encamped near the river Oxus, two springs rose out of the earth near Alexander's pavilion, the one of water and the other of oil, of which prodigy Ptolemy Lagus forthwith informed the king as soon as he heard of it, whereupon Alexander, without delay, at the command of the priest, sacrificed. Aristander, the priest, told the king

that the fountain of oil portended labor, but victory at last—the fruit of toil and pain."

This locality is not very distant from Baku, the seat of the present great Russian oil fields, but lies to the east of the Caspian sea.

Plutarch, in his life of Alexander, gives the following version of the same story: "A wonderful thing happened not long after and was thought to presage better for Proxenus, a Macedonian, who was chief of those who looked to the king's furniture. As he was breaking up the ground near the river Oxus, to set up the royal pavilion, he discovered a spring of a fat, oily liquor which, after the top was taken off, ran pure, clear oil, without any difference either of taste or smell, having the same smoothness and brightness, and that, too, in a country where no olives grow. * * * The diviners told him that it signified his expedition would be glorious in the event, but very painful and attended with difficulties, for oil, they said, was bestowed on man by God as a refreshment of his labor."

Marco Polo (Book 1, chap. IV) refers to the Assyrian locality as follows: "Bordering upon Armenia to the southwest are the districts of Mosul and Mardin, which shall be described hereafter, and many others too numerous to particularize. To the north lies Zorania, near the confines of which there is a fountain of oil that discharges so great a quantity as to furnish loading for many camels. The use of it is not for the purpose of food, but as an unguent for the cure of cutaneous distempers in men and cattle, as well as other complaints. It is also good for burning; in the neighboring country no other is used in their lamps, and people come from distant parts to procure it."

This in all probability refers to the Baku oil districts on the shores of the Caspian sea.

John Cartwright mentions the same locality in his travels: "Near to this place is a very strange and wonderful fountain underground, out of which there springeth and issueth a marvelous quantity of black oil, which serveth all the parts of Persia, to burn in their houses, and they usually carry it all over the country upon kine and asses, whereof you shall oftentimes meet there three or four hundred in company."

John Gadbury (The Nature of Prodiges; London, 1660), has written the following (fol. 55): "In A. D. 323 a fountain ran with oil in Italy." In the same curious book may be found the following (fol. 9): "It is also prodigious for wool and oyl to be poured down from the skye on the earth, as at Velos, a city of Hetruria, in Anno mundi 3842, it rain'd oyl extremely;" and fol. 64, "A. D. 746, oyl rain'd in Spain."

Naphtha is a Latin word derived from the Greek; it was also called *oleum incendiarium* and *oleum vitum*.

The ancients were familiar with localities and the nature of naphtha, but we have, I believe, no record of their having made use of it, as the mediævals certainly did. The following quotations embrace all of interest I have been able to gather:

According to Strabo (Book 16, chap. I-XV) "asphaltus is found in great abundance in Babylonia." He quotes Eratosthenes as follows: "The liquid asphaltus, which is called naphtha, is found in Susiana. * * * The liquid kind called naphtha is of a singular nature; when brought near the fire the fire catches it, and if a body smeared over with it is brought near the fire it burns with a flame which it is impossible to extinguish except with a large quantity of water; with a small quantity it burns more violently, but it may be smothered and extinguished by mud. * * * Poseidonius says there are springs of naphtha in Babylonia, some of which produce white and others black naphtha. The first of these, I mean the white naphtha which attracts flame, is liquid sulphur; the second or black naphtha is liquid asphalt and is burned in lamps instead of oil."

Pliny (Natural History, Book 2, chap. CIX): "Naphtha is a substance of a nature similar to maltha. It is so called about Babylon and in the territory of Astaceni in Parthia, flowing like liquid bitumen. It has a great affinity for fire, which instantly darts on it whenever it is seen. It is said that in this way it was that Medea burned Jason's mistress, her crown having taken fire as she approached the altar for the purpose of sacrificing."

Book 35, chap. LI: "Some authorities include among the bitumens, naphtha—a substance we have already mentioned in the second book—but the burning properties which it possesses and its susceptibility of igniting render it quite unfit for use."

The following is from Plutarch's life as Alexander: "From hence he marched through the provinces of Babylon, which immediately submitted to him, and in Ecbatana was much surprised at the sight of the place where fire issues in a continuous stream, like a spring of water out of a cleft in the earth, and the stream of naphtha which is not far from this spot flows out so abundantly as to form a sort of lake. This naphtha in other respects re-

sembles bitumen; is so subject to take fire that before it touches the flame it will kindle at the very light that surrounds it, and often inflame the intermediate air also. The barbarians, to show the power and nature, sprinkled the street that led to the king's lodging with little drops of it, and when it was almost night stood at the end with torches, which, being applied at the farther end of the moistened places, the first taking fire, instantly, as quick as a man can think, it caught fire from one end to the other in such a manner that the whole street was one continued flame.

"Among those who used to wait on the king and find occasion to amuse him when he anointed and washed himself, there was one Athenophanes, an Athenian, who desired to make an experiment of the naphtha upon Stephanus, who stood in the bathing place—a young man with a ridiculously ugly face, whose talent was slinging well—"for," said he, "if it take hold of him and is not put out, it must undeniably be allowed to be of the most invincible strength." The youth, as it happened, readily consented to undergo the trial, and as soon as he was anointed and rubbed with it his whole body broke out into such a flame and was so seized by the fire that Alexander, in the greatest perplexity and alarm for him, and not without reason, for nothing could have prevented his being consumed by it, if by good chance there had not been people at hand with a great many vessels of water for the service of the bath, with all of which they had much to do to extinguish the fire, and his body was so burned all over that he was not cured of it for a good while; and thus it is not without some plausibility that they endeavor to reconcile the fable to the truth who say this was the drug in the tragedies with which Medea anointed the crown and veil which she gave to Creon's daughter, for neither the things themselves nor the fire could kindle by its own accord, but, being prepared for it by the naphtha, they imperceptibly attracted and caught a flame which happened to be brought near them."

Creusa, sometimes called Glauce, according to the myth, was about to marry Jason. Medea prepared a garment, said to have been poisoned, but believed by others to have been saturated with naphtha, which Creusa had no sooner put on than it burst into flames and caused her death.

The version by Diodorus Siculus of this myth is as follows (Book 4, chap. IV): "Medæa therefore being commanded to leave the city, having only one day allowed her by Creon to prepare for her departure, by the art of witchcraft she changed the form of her countenance and entered the palace in the night, and by a root, found out by her sister Cerces (which, being kindled, could not be extinguished), she set fire to the palace; now, all being in a flame, Jason sprang from the burning and so escaped, but Glance and her father Creon, hemmed in on every side by the fire, were both consumed."

(To be continued.)

Nitrate Beds in Colombia.

Immense nitrate of soda deposits have been discovered recently in the United States of Colombia, South America. As these beds are situated on or near navigable rivers, which run into the Caribbean sea, they are thus over 2500 miles nearer the markets of the United States and of Europe than the Chili fields of niter.

The new nitrate beds are about 30 square miles in extent, and are from one to ten feet in thickness. They lie at Val du Tar, south of the spurs of the Sierra Nevada de Santa Marta, a distance of 65 miles from the city of San Juan de la Ciénaga, and are in part on the waters of the San Sebastian river, which flows into the great sea level lake of Ciénaga Grande, which is in the extreme northern portion of the Republic. These nitrate fields can be placed upon a direct line of inland navigation by connecting the waters of the Aracataca river with those of the San Sebastian, at a cost not exceeding \$5000. When the Santa Marta seaport railway is finished, it will run to the village of Fundacion, and within half a mile of the nitrate beds.

These deposits lie at a depth of from 8 to 20 feet below the surface and rest on a stratum of carboniferous sandstone. The caliche or saliterras itself contains, besides the niter, calcium sulphate, calcium carbonate, iron oxide, salt and magnesite. The deposit appears to be of recent date, and it is evident that the nitrate has been produced by the chemical reactions of vegetable substances and lime in its various forms.

These deposits promise a supply of over seven billion tons of caliche, assaying 11½ per cent of saltpeter on an average to the ton of raw material; 100 parts of the caliche contains eleven parts of niter and two parts of phosphate. The calcium phosphate is fossil bone, and assays 55 pounds to the ton of caliche. It will cost from \$8 to \$11 per ton to separate the pure nitrate from caliche and deliver it in New York City.

Folsom's Former Gold Yield.

"E. C. R." in the Sacramento Bee.

As near as can be ascertained, the first mining of any consequence done in the vicinity of Folsom was in the year 1854, when gold in large quantities was discovered on what was designated Nigger Bar, situated about half a mile from the present location of the town. Within a short period of the discovery over one thousand men were working on the bar, and it is safe to say that the output was at least a half an ounce per day to the man. At that time all the mining was done on the river bars, and it was not long before the diggings on Beals, Condemned, Rattlesnake, Bean, Mississippi, Sallor and numerous other bars along the American river were discovered and populated by crowds of eager miners delving for the golden sands.

As the bars became exhausted prospects were made in the surrounding country, and the mining districts of Rebel Hill, Prairie City, Nigger Hill, Rhodes, Willow Spring and Walltown were found to be enormously rich. It would be simply impossible to accurately ascertain the amount of gold produced within the last 40 years from this large out-

month, after paying all expenses, found himself \$4000 in pocket. About a week later portions of his mine caved in, caused by insufficient timbering, and he expended the majority of the money before extracted in retimbering and clearing out the debris. Shortly afterward the Chinese declared that the pay streak had "pinched out," and he eventually sold his interest to another company of Chinese for the sum of \$300. Within a month this company and the Chinese who had been in his employ cleaned up over \$76,000, and selling out, returned to China. Then it was discovered that his former employes had simply drifted over the gold, leaving it on the bedrock, and, through emissaries, had purchased all the right and title, and, to use a popular expression, "scooped the whole cheese."

Next to Beale's Bar, which is conceded to have been the richest deposit along the American river, Buckeye Bar was probably the next on the list. It gave an output of \$700,000 the first season, and during the first five years it was mined the books of the company owning it showed a production of \$3,000,000.

Main Bar is reputed to be enormously rich; but, owing to the depth of the debris deposit, and the narrow confines

sinking a shaft near Mormon Island and in close proximity to the river when he was approached by a tenderfoot who asked if he could inform him where he could dig a hole and get some gold.

"Yes," was the answer, "dig right over there," tossing a small stone to designate the spot, and so close to the river as to lead the experienced miner to suppose that the tenderfoot would be flooded out after he had dug a few feet; but, on the contrary, the tenderfoot, at the depth of 20 feet, struck a pot-hole and panned out \$10,000, while the old miner did not extract gold enough from his shaft to pay for his grub stake.

The majority of the gold that has been produced in the environs of Folsom during the mining period has been washed from the earth, and but little attention has been paid to the different quartz veins that seam the country in all directions, except by pocket hunters, many of whom have been and are extracting considerable sums at times, and yet in the Rhodes digging district, and throughout Walltown, there are numerous holes of gold-bearing rock that only await capital and enterprise to yield in paying quantities.

Of the present producing mines, perhaps that owned and operated by Messrs. White and Donnelly is giving the largest returns. These gentlemen employ about 20 men and wash up on an average once a week. Some Chinese in the same locality have a very rich mine, but decline to allow any investigation to determine the amount derived.

The mine operated by Jackson and McCue, although at great expense, on account of the large quantities of water encountered, is paying well. Nearly all the old localities have some good claims left which turn out yearly a regular sum; and, although it is a thing of the past for one to take a pan or a rocker and make an ounce a day, yet the environs of Folsom will yet demonstrate that not all the gold was extracted in the days gone by, and that with the expenditure of but little capital the lower strata, which have never been reached, will yield a rich return.

Combined Punch and Shears.

On this page is illustrated a combined punch and shears, designed for general work in either boiler or structural shops by the Hilles & Jones Company, Wilmington, Del. One end of the machine is fitted with knives for trimming plates. This end can also be arranged with knives and blanks for cutting off round or flat bars, or with a punching arrangement, as may be desired. The other side of the machine is arranged with a cast steel overhauling die block used for punching channels, I beams, angles, flanges, etc. There is a filling piece which can be used under the overhauling die block when preferred, when channels and I beams are not being worked. Both ends of the machine are independent of each other, both being controlled by clutches faced with steel. The depth of throat of the machine shown in the cut is 30 inches on each side. The weight is about 33,000 pounds. The proportions of gearing, arrangement of the metal to take the strains and all other points of detail have been carefully worked out. The sliding head is counterbalanced through a tension spring and has a taper brass shoe for taking up the wear.

Coal Consumption of the Columbia.

The official report of the inspection at sea of the cruiser Columbia shows that she is incomparably the most economical naval vessel in the world.

Four trials of six hours each were conducted. In the first, with three engines, she ran at the rate of 16.41 knots, with a coal consumption of 125.6 tons per day. Two machinists and six men then disconnected the twin wing screws in 40 minutes, and then followed a six hours' run, using only the single central screw, developing a speed of 10.06 knots, and consuming coal at the rate of 38.3 tons per day. The third trial was with all three engines, during which the remarkable speed of 18.4 knots was maintained for six hours, the coal consumption rising to 223 tons daily.

Then one machinist and three men disconnected the central screw, and on the two remaining engines, with 70.2 tons daily coal consumption, a speed of 13.56 knots was recorded.

The great efficiency of the ship is apparent when it is considered that the coal bunker capacity of the ship is 2450 tons, which, with the central screw for ordinary cruising purposes, gives the vessel a steaming radius of nearly 12,000 miles, unequaled by any vessel afloat.

THE most widely separated points between which a telegram can be sent are British Columbia and New Zealand. The telegram would cross North America, Newfoundland, the Atlantic, England, Germany, Russia (European and Asiatic), China, Japan, Java and Australia. It would make nearly a circuit of the globe, and would traverse over 20,000 miles in doing so.

COMBINED PUNCH AND SHEARS.

lying district, as many of the early miners carried their dust with them when they left the diggings for other localities.

The only authentic information obtainable is derived from the books of the Wells-Fargo Express Company. According to these records the output handled by this company from 1856 to 1866 averaged \$80,000 per month; from 1866 to 1876, \$50,000 per month, and from 1876 to 1886, \$30,000 per month, while from 1886 to the present date the product has dwindled down to about \$15,000 per month, giving an approximate of \$20,640,000 that has passed through the hands of this company alone.

J. Hyman, who was probably the next largest purchaser of gold dust, states that he bought on an average the first ten years he resided in the town \$150,000 worth per year. The next ten years he handled on an average \$100,000 per year, while he has purchased during the last ten years but about \$40,000 per year, making a total of \$3,900,000.

It is impossible to estimate the vast sums of gold that have been extracted and taken away by the Chinese during the last 40 years, but they must have been simply enormous. In 1878 there were over 3000 Chinese mining in and around Folsom, many of whom returned year after year to their native land independently rich. It is stated that a resident of the town, since deceased, sank a shaft and struck a streak of pay gravel. He immediately hired a number of Chinese to work under ground, and the first

of the river, it cannot be worked. One company did succeed in striking bedrock during a dry season, and, with three hours' work, took out over one hundred ounces of gold; but the river rose that night and flooded them out, and, although numerous attempts have been made to mine it since, none of them have been successful.

Willow Spring Hill, situated about three miles from Folsom, was for years one of the richest paying localities of this mining section. The mines were known as bank claims, and were from 30 to 40 feet in height, the gold-bearing gravel being in strata throughout the entire bank. Into these banks tunnels were run, and large quantities of powder used to blast down the dirt. After it was loosened it was hydraulicked through boxes lined with riffles, where the fine gold was amalgamated with quicksilver.

The mines of Prairie City and the adjacent ones of Rhodes' diggings were marvelously rich, producing very coarse gold. Nuggets worth as much as \$700 have been found in this section, and it has been customary for years for resident miners to search the surface after heavy rains and pick up exposed nuggets.

Mormon Island also produced vast amounts of gold during early days, as did also Mississippi and Silver Bars. These latter places are still being mined, and in spots produce well.

Many are the interesting tales related by old miners of rich strikes made in earlier days. One old pioneer was

Scientific Progress.

The Life of the Flesh.

The French call the blood "running flesh;" the Bible calls it "the life of the flesh." To the naked eye it is a crimson fluid. A drop of it under the microscope shows a nearly colorless fluid, in which float cells, called red and white corpuscles and blood plates. The red corpuscles look red only when seen in a mass; when examined under the microscope they are a pale amber color. There are about three hundred times more red corpuscles than white, but they are slightly smaller. A cubic inch of blood contains seventy times as many red corpuscles as the world does inhabitants. Their special mission seems to be to carry oxygen. They get a good supply in the lungs, and rush off brisk and rosy; they return blue and loaded with the poisonous refuse for which they have exchanged part of their oxygen. They are exceedingly busy, for they must make the trip from the lungs and back in about two minutes. Perhaps the tiny red corpuscle has had to rush through arteries and capillaries to the tip of your little finger, then back through the veins to the heart, and from there to the lungs.

If you would like to know what the effect would be should these faithful servants be unable to perform their task, wind a piece of twine several times around your finger, so that the red corpuscles cannot return to the lungs for a fresh supply of oxygen. In a short time your finger swells and turns purple. If the twine is wound tightly enough and left long enough, your finger may die and actually mortify. But you will hardly care to carry the experiment so far, but will be glad to set the little corpuscles free and let them hurry back to the lungs for a fresh load of oxygen.

The white corpuscles are cells of protoplasm, having their own work to do. Now they carry needed supplies to a nerve, now to the brain, now to a bone, building up and repairing unceasingly.

The fluid in which the corpuscles float is called blood plasma. Among other things found in it is a substance called fibrinogen, which has saved your life by keeping you from bleeding to death when you have cut yourself or have had a tooth pulled. It aids in clotting the blood, and so stops its flow. The most skillful surgeon would be unable permanently to stop the bleeding without the help of the soft, curly threads of fibrin which are formed in injured blood.

A strong muscular bag, about as large as your fist, is the powerful force pump which sends the blood on its journey to the different parts of your body. Put your ear close to some one's left side and listen to the regular rhythm of the heart performing its wonderful work.

THERE has recently been successfully treated at Halloway, near London, the largest balloon in the world. It has a capacity of 100,000 cubic feet, weighs 2250 pounds, and will lift an additional ton. It is to be used in making meteorological observations for a period of six days without descending.

A LARGER wheel than the great Ferris wheel is being erected at Earl's Court, London. It is a 400-foot wheel, and will carry 2000 people in fifty cars. Three restaurants will be built on platforms at varying heights on the supporting towers, and a ballroom will crown the towers at the axle.

A GERMAN army officer has invented a motor in which a fine stream of coal dust is utilized to drive a piston by explosion in the same manner as the gas in the gas engine.

THE use of brick-dust mortar as a substitute for hydraulic cement, where the latter cannot be obtained, is recommended by the best engineering authorities.

Growth of the Telephone Business.

When the inventor of the telephone first made known his discovery eighteen years ago it probably did not enter into even his sanguine expectations that his scheme of conveying speech by electricity would have the success it has since reached. If it had been made known first in a European country it would have enjoyed a certain measure of prosperity, limited, however, by the conservative character of the people and the difficulty of adjusting the business and social life in an old country to a new and startling change. It would have caused a jog in the life of the people such as the breaking off of a sharp bluff causes in a landscape.

But that is not the American way. The distinguishing American trait is to grasp eagerly at any innovation that holds out the promise of saving time and money. The only questions asked are: Will it be useful and will it pay? The seventeen years' use of the telephone proves that both these inquiries have been answered affirmatively. In December, 1877, a year and a half after the patent was issued, there were 5,000 telephones in use. A year later there were 52,000, and from that time on the increase has been by great strides, until to-day there are nearly 600,000 telephones in daily use in this country. The exchange system has grown from 138 exchanges in 1880 to 1400 in 1893, but the increase of subscribers to the exchanges has been much greater, the number in the United States being estimated at 240,000.

The use of this time and labor-saving invention has been greater still. In 1884 the number of telephone conversations was estimated at 215,000,000, but last year the conversations were estimated at 650,000,000, or an increase of 200 per cent., the growth of the population of the country during the ten intervening years being about 20 per cent probably. A comparison with the use of the telephone in European countries will show how much more rapid a useful invention is taken up in this country than abroad. In 1892 all of France had only 146 telephone exchanges and 20,000 subscribers, or less than half the number in New England. In all Great Britain there are 45,000 subscribers, or only one-fifth as many as in the United States. Germany has about 85,000 subscribers and Italy some 15,000. The total number of subscribers in all Europe is not more than 80 per cent of the number in the United States alone.

The financial success of the telephone has been as great as its adaptability to the wants of the public. The company that controls the telephone in this country was organized in 1880 with a capital of \$6,500,000, which had increased last year to \$20,000,000. The dividends paid during that time range from \$178,000 in 1880 and 1881 to \$3,337,500 in 1893, or a total of dividends in 14 years of \$23,106,560, and a yearly average of \$1,650,435. Such an enormous return from the creation of one man's mind rivals the glories of the achievements of Aladdin's Lamp. But while the American people are far ahead of the Europeans in the use of the telephone, the latter appear to have beaten us in cheapness. The annual rental of a telephone at a place of business in Philadelphia is \$140. In Boston the same service costs \$156 to \$180.

But in Switzerland, for instance, the use of a telephone can be had for \$16 a year. It is probable, however, that in this case the talker and the listener must go into the general stations and take their turn, instead of having a private instrument connected with a general exchange, an inconvenience that an American would not submit to. The expirations of patents, improved methods and the general cheapening of the whole process must in the near future reduce the cost of this useful service and bring it into more general use. How complicated the telephone system will then become can be estimated from the fact that on one switchboard

in a single Boston station there are 400,000 connections.

A NEW and what must prove to be an interesting field for investigation has just been suggested, namely, that of the psychology of the weather. A few observers have already paid some attention to it, and so far the results of their inquiries would appear to point to the fact that many very powerful forces, coming from what is popularly called the weather, control the operations and success of brain-workers. Experimenters and others engaged in mental tasks of an exacting description have found faulty deductions and misconception to be the result of their work in damp, foggy weather, or on days in which the air was charged with electricity and thunderstorms were impending. Indeed, deductions which seemed clear at these times appeared later to be filled with error. An actuary in an insurance company is obliged to stop work at such times, because he finds that he makes so many mistakes. A further confirmatory fact is that in large factories from 10 to 20 per cent less work is accomplished on damp days and days of threatening storm than when the weather is fine.

Professional.

ELECTRICAL ENGINEER.

C. PER LEE NIXON,
628 Mission Street, San Francisco,
Consulting Electrician. Dynamo and Instrument repairing a Specialty. Correspondence Solicited.

F. ORTON, Mechanical Engineer.

EXPERT DESIGNER of Special and General Machinery.
PREPARING PLANS of Steam, Air and Hydraulic Apparatus, Iron and Wood-Cutting Machines, Transmission of Power, Etc.

ASSAYING AND ANALYSIS.
"Consulting Associate Mining Attorney at Law."

Will examine and report upon "Title and Exact Value" of GOLD, SILVER, LEAD, COPPER, COAL, IRON, CLAY or other MINERAL PROPERTIES in any part of the world. Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.

DR. WILLIS E. EVERETTE, 1818 E. ST.,
Tacoma, State of Washington, U. S. A.

INSTRUCTION BY MAIL

IN ARCHITECTURE, ARCHITECTURAL DRAWING, PLUMBING, HEATING and VENTILATION, BRIDGE ENGINEERING, RAILROAD ENGINEERING, SURVEYING and MAPPING, ELECTRICAL ENGINEERING, MECHANICAL DRAWING, MECHANICS, ENGLISH BRANCHES, and

MINING.

Diplomas awarded. To begin students need only to know how to read and write. Send for FREE Circular of Information, stating the subject you think of studying, to The Correspondence School of Mechanics and Industrial Sciences, Scranton, Pa.

4000 STUDENTS.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., PATENT AGENTS,

220 Market St., Elevator, 12 Front St., S. F.
TELEPHONE No. 658.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$6.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

GEO. E. BELMOR,

OF THE BELMOR BOILER WORKS,
Has Removed from 210 Mission St. to 52, 54 and 56 Blinome St., bet. 4th and 5th.

(To the old H. W. Rice Machine Works.)
FOR BOILERS, DREDGING BUCKETS and SHEET IRON WORK, CORRESPOND.

Mechanical Progress.

Artificial Stone.

The manufacture of artificial stone and concrete in various forms has been practiced almost since the art of building has been known, but some German makers have hit upon a plan of imitating nature which is worthy of some notice as being out of the common. This contains from two to three parts of clay, and, when well dried and screened, it is placed, with a certain proportion of ground lime, into an iron drum kept revolved, so that the materials are thoroughly mixed together. Subsequently the mixture is removed, placed in molds, which, after being screwed down tightly, are placed in a cylinder into which water and steam are admitted. The water covers the molds, and the steam is forced into the cylinder at a pressure of 45 to 60 pounds the square inch. The steam forces the water between the crevices of the molds, the water slakes the lime, causing it to expand in volume, and as the molds resist the outward expansion the lime is forced into the sand and cements it into a hard stone. After the steam pressure has been kept for three days the molds are removed and allowed to cool for 12 hours before being opened, and then the stone is removed. Various colors can be obtained by the mixture of colored earths with the sand and lime in the cylinders. Experiments made to determine the resistance to thrusting stress of six-inch cubes of this artificial stone show that on an average three cubes of buff color crushed at 196.6 tons per square foot, while other three cubes of gray went at 186.6 tons. The stone is thus shown to be of considerable strength, while in appearance it very closely resembles natural sandstone, though somewhat more uniform in grain and texture.

Electricity's Possibilities.

Of the possibilities of electricity the prospectus of a proposed "national school of electricity," to be established at Chicago under the auspices of Edison and a number of other eminent electricians, says: "More than \$800,000,000 is employed in electrical pursuits to-day, and these figures are being increased at the rate of \$100,000,000 annually. Within a decade nine-tenths of the steamboating, railroading, canal hauling, illumination, domestic lighting, heating, cooking, factory operation, milking and machinery will be done by electricity. There are also many applications of electricity yet in an undeveloped state. Electricity is the most promising field in civilization to-day."

While the prediction that within ten years "nine-tenths of the steamboating, railroading, canal hauling, etc." will be done by this wondrous agency will doubtless prove extravagant, it is certain that the application of electricity to the practical arts is still going on, and none may venture to fix its limitations. In the single direction of urban and rural railway transportation the electric motor has made astonishing advances within the past ten years, and who can say that it may not eventually supersede the steam locomotive?—*Railway Age.*

The Trade in Flints.

The oldest industry in Great Britain—older it could hardly be, for its existence has been traced back to the pre-historic stone age—is still being carried on at the village of Brandon, on the borders of Norfolk and Suffolk, and is reported to be in a flourishing condition. It is the manufacture of gun and tinder-box flints. The work is done in little sheds, often at the back of townsfolk's cottages. It will naturally be asked, "Who wants tinder-box flints and gun flints in these days of phosphorus matches and Martin-Henrys?" The answer to the first question is that there is a good trade in tinder-box flints with Spain

and Italy, where the tinder-box still keeps its ground in very rural districts. Travelers in uncivilized regions, moreover, find flint and steel more trustworthy than matches, which are useless after they have absorbed moisture. Gun flints, on the other hand, go mostly to the wild parts of Africa.

Exclusively Electrical Power.

The new Postal Telegraph building on Broadway, New York, is, of course, lighted by electricity, and it is also the intention to use part of the current for heating and in time for cooking in the kitchen of the Hardware Club on the top story. All the elevators are run by electricity, and the same isolated plant in the basement which furnishes the current for light, heat and fan motors also operates these elevators and drives a large bank of "dynamotors," which in turn deliver current to all the different telegraphic circuits, dispensing entirely with the old-time gravity batteries. Another feature is that the electric elevators are being placed under push-button control, so that the elevator men, instead of working a lever or opening a valve, merely press a row of three buttons. This is not all, as a new device is being introduced by means of which any one waiting in the halls or on any floor can signal the next elevator coming his way to stop for him. In the operating room the message forms are distributed by a pneumatic tube system which is under electromagnetic control. Not only are incandescent lamps in use, but in the larger spaces, such as the receiving department, dynamo room, hallways, etc., arc lights are employed, all operated on the same circuit by the same current.

Lick School of Mechanical Arts.

'Tis nearly twenty years since Jas. Lick left large sums for sundry local public purposes, but several of the bequests are yet devoid of tangible form. The Lick School of Mechanical Arts has the present attention of the trustees, and a three story building 70x125 feet will be built this summer. The clay modeling department, cooking rooms and chemical laboratory will be in the basement. The science reception room, library and museum will be on the first floor. The serving rooms, mechanical drawing departments, iron and wood shops, etc., will occupy the remainder. Geo. A. Merrill, recently principal of the Cogswell school, will be principal.

A CORRESPONDENT of *Engineering* thus describes the means used for removing a shrunk on crank disk from a shaft, the shaft being in place. He says: I solved the problem, however, by drilling a 3/4-inch gas-tapping hole eight inches up the end of the engine shaft, tapping the end of the hole, and inserting three feet of 3/4-inch tube. Up this tube and hole I passed a five-foot length of 3/4-inch tube, connected at its outer end to a flexible water-hose. A good fire under the crank disk, and a plentiful stream of water up the hole in the shaft, soon did all that was necessary, and the disk was removed without further trouble. The 3/4-inch tube merely served to keep the water off the fire.

THE last census report gives \$36 per horse power per year of 313 days at ten hours per day as the average cost of steam power in the United States. This is equal to 1.15 cents per horse power per hour. It is reported that power is being contracted for at Niagara at from \$8 to \$24 per horse power per year of 365 days, counting 24 hours to the day, no additional charge being made for nights or Sundays, as the waterfall "goes on forever."

DR. SCHEELE, a New York chemist, has discovered that telephone transmitters, especially in public places, swarm with bacteria, and may transmit deadly disease as well as

sound. Diphtheria, scarlet fever and small pox are among the contagious diseases liable in certain cases to be propagated by an unclean telephone transmitter.

Metallurgy and Ores.

SELBY SMELTING AND LEAD CO.

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

—AND—

ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF—

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

—ALSO MANUFACTURERS OF—

Standard Shot - Gun Cartridges,

Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals. Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co., and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day. It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it. Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

M. A. GRAHAM,

Inventor and Manufacturer,

105 BEALE STREET, SAN FRANCISCO.

HEALD'S BUSINESS COLLEGE.

24 POST STREET, SAN FRANCISCO.

FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing, Book-keeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils. Our school has the graduates in every part of the State. SEND FOR CIRCULAR. E. P. HEALD, Pres. O. S. HALEY, Sec.

Electric Progress.

Speed of Ocean Telegraphy.

Soon after submarine telegraph became a practical success it was discovered that the wire used for that purpose would not work as well as a land wire. With the best trans-Atlantic cables only from 25 to 30 words a minute can be transmitted intelligibly; on land lines the only limit is the skill of the operator or the speed of an automatic machine for transmitting, which latter often reaches 200 or 300 words a minute. The difficulty in cabling, long considered insurmountable, is due to the fact that an ocean wire has an insulating coat of gutta-percha; and this develops on its outer surface a certain amount of negative electricity, by induction, every time that positive electricity is sent into the wire. The phenomenon is the same as that witnessed on the outside of a Leyden jar when the inner coating is charged. It may also be observed in an instrument called the condenser. Therein a number of metal plates are separated from each other by insulating material, and alternate ones are connected among themselves, and with a common wire. Fill up one set of plates from the positive pole of a battery or dynamo, and in the other an equal amount of negative electricity will be excited. The copper core of a cable, then, is not only a conductor, but, in combination with its coating, it is also a sort of reservoir or sponge. Hence, before any of the current put into it at one end can come out at the other, a certain amount of electric energy must be consumed in the inductive process. Of course this is done very quickly; but it requires an appreciable length of time and wastes just so much current, and the longer the cable the greater the loss of time and current. Length increases the storage possibilities of this quasi Leyden jar. Unless the opening and closing of the circuit by the sender are done slowly enough, therefore, either no signals at all will be observed by the receiving operator, or else they will be faint and indistinguishable.

Now, if there could be devised a way to reduce the "electrostatic capacity" of the cable, less current would be absorbed and more would be delivered for effective use at the end of the line. Dr. M. I. Pupin of Columbia College, whose original investigations of electrical phenomena for the last two or three years have attracted wide attention, now proposes such a method. He would introduce into the line, at frequent and regular intervals, these very instruments to which reference has just been made, namely, condensers. The current sent into the first of these sections will not pass into the second, since the two sets of plates in the condenser would be insulated from each other. But a secondary current would be induced in the interposed instrument, and this would traverse the next section. Thus each portion of the line would act upon the one beyond it, so that electric action would still be manifest at the terminus as if there were a continuous conductor. One result of this arrangement would be that the electrostatic capacity of the cable as a whole would be limited to that of any one of those sections, and hence reduced to almost nothing; and that energy-absorbing phenomenon of "line" induction would be avoided. The signaling service would be performed through the inductive action of the condensers proper, and these would purposely have ample capacity, greatly exceeding that of the wire actions.

At each junction in the line a short side-track or shunt would be put in, and made to include an induction coil of enough resistance to refuse to take the main current, so long as the current was in working order. But if the latter should break down, no other route would be open, and the current would then flow through the coil into the next section.

In long distance overland telephony, as

well as in submarine telegraphy, trouble is now experienced from induction; and this puts a limit on the length of a line that can be successfully operated. At present human speech is not now transmitted more than about 1000 miles. Dr. Pupin, however, believes that his invention removes that obstacle, and that it opens the way also to ocean telephony. By a simple adjustment of apparatus he thinks the same wire may be used for both telephones and telegraphs. The cost of the appliances here mentioned introduces a commercial factor of such importance that the practical application of this idea to submarine wires may be deferred for a long time, perhaps, even though it be feasible electrically; but technical publications of high standing regard with favor the suggestion of trying it in telephone service. Here, again, the question of expense will come in. Scientifically, however, the principle is admitted to be sound.

An essential feature of this system is the "tuning" of the sections composing the line. In some recent experiments Dr. Pupin employed a circuit into which he had introduced a condenser and a self-induction coil. He then showed that such a circuit had a natural "period" of its own; that is, it would more easily transmit an alternating current of a particular frequency than one of any other frequency. If, though, he modified the capacity of his condenser, or the effect of his induction coil, the period could be changed just as the tone of a piano or violin string could be varied by altering the tension. This, then, is what he means by "tuning" an electric circuit, and, by carefully calculating the capacity of the condensers inserted in an ocean cable, the sections could be easily tuned as desired. Such adjustment would be necessary for either ocean telegraphy or overland telephony alone; and if a cable were to be used for both telegraphic and telephonic purposes, a special transformer, into which four small condensers were introduced for tuning it, would also be required at the starting point.

The condensers for submarine use, says the originator of this system, would not be the large, box-like instruments seen in laboratories, but small cylinders, or rolls of ribbon-like plates, wound about the core. About 20 of them, arranged an inch or two apart along the wire-like heads, would, he says, give the required capacity. They need not have a cross section greater than that of an ordinary cable. These groups ought to be introduced at intervals of several miles for Atlantic service, and Dr. Pupin thinks that such a cable might be constructed for only twice the cost of those now in use. On a longer line, say across the Pacific, it would be desirable to put in a proportionately larger number of groups of ribbon condensers. It has been said, at the beginning of this article, that with machines (such as the Wheatstone) 200 or 300 words a minute may be transmitted over land lines by telegraphy. On a short circuit (of a mile, for instance) such apparatus would transmit 600 words a minute, says J. C. Knikel, one of the Western Union electricians in New York. Certain conditions incident to a long line make it desirable, if not necessary, to reduce the speed. To Chicago, 200 words a minute is an average rate from New York; to St. Louis, 175; to Boston, perhaps 300 words might be sent. But Dr. Pupin thinks that his system would make it possible, both by land and sea, to transmit 500 or 600 words a minute! As yet, however, no actual test has been made on long ocean cables.

Dr. Pupin has also had in view, in devising this apparatus, the electric lighting of harbor buoys. Such buoys, whenever tried, have been supplied with an alternating current through a cable resembling that employed for telegraphing across the Atlantic; and the difficulties incident to thus transmitting the electric fluid have threatened to render the whole idea impracticable. With

a "tuned" cable, though, the problem is solved. Hence the principle of "resonance," to employ another musical simile, here finds one more useful application.

Comparative Cost of Electrical Equipment.

A recent number of the *Electrical Review* contains the following interesting matter in relation to the comparative cost of electrical equipment of street-car systems now and a few years ago: "Six years ago the price for a complete equipment for a trolley car, including two motors, was about \$4500. This price held for a year and a half, and then dropped to \$3850, \$3500 and \$3300, until, two years ago, it was about \$2850. One year ago \$2000 was the price of the same equipment, greatly improved in quality and efficiency, while to-day the average price is between \$1000 and \$1200. We have been told of an electric railway manager who desired quite recently to purchase an equipment for a single car. He wrote to seven manufacturing companies and immediately was called upon by seven salesmen, all of whom had paid traveling expenses to try for the order. The prices ranged from \$1500 to \$640. The manager bought the \$640 apparatus. Here we have a decrease in actual selling prices from \$4500 in 1888 to \$640 in 1894, a period of six years. In 1888 there were seven electric railways in operation and in process of construction. In January, 1890, there were 162 electric railways in operation and in process of construction. In January, 1891, this number had grown to 281, while to-day there are probably over 500 cities in the United States equipped with electric roads, many of them of great mileage, as in Boston, Brooklyn, St. Paul, Minneapolis and Cincinnati.

New Atlantic Cable.

It is expected that the new Atlantic cable, the third and largest of the trans-Atlantic news-carriers, will be completed to-day. The steamer Faraday has been engaged in reeling out the new cable from the coast of Ireland to Canso, Nova Scotia. One hundred miles on the Irish coast and 400 miles out from Nova Scotia were run out first and then the 1500 miles connecting the two "huoyed up" ends.

IN REPLY to a suggestion made by the *American Machinist* that all steam fire engines should be self-propelling, a correspondent of the *Electrical Review* proposes that fire engines be operated by electricity. His fire engine would be an electric pump mounted on a light truck. A system of electrical supply similar to a lighting system would furnish current. Switches enclosed in accessible boxes on the streets would be distributed the same as the fire hydrants. After the engines had been run to the fire, presumably by horses, connection between the electric pump and the street switch would be made and there you are.

SELDOM is noticed mistakes in other papers, for all mankind is prone to err, but the following from *Pearson's Weekly*, an English publication, is so irresistibly funny that it is given place. Talking of mica, our trans-Atlantic contemporary says: "Mica is chiefly made use of for dynamos, electric alternators and transformers, and also for placing at the ends of cables for the purpose of absorbing the electricity which lingers in the wire after a message has been sent, the presence of which would affect subsequent messages."

IT IS probably not widely known, says the *Electrical Review*, that only seven out of the 17 trans-Atlantic cables are in use—ten having given out from various causes. Estimating the cost of each cable at \$3,000,000, here is an irreclaimable investment of \$30,000,000 safely buried beneath the ocean to a depth ranging from a few fathoms to over five miles.

Practical Information.

From Grains of Wheat to Flour.

One who has never been in a flouring mill of the largest size cannot realize what a peculiar lot of noises are made by the machinery. As soon as the wheat enters the machine from the long spout which brings it down from the upper floors, it falls between two rollers of iron—"chilled" iron, they call it, and very hard iron it is, too. One of these rollers revolves rapidly, the other more slowly, in order that the separation of the coat, or bran, from the kernel may be more easily accomplished.

The wheat first passes between rollers separated just enough to allow the coat to be crushed. It is then carried away up to the top of the mill again to a room where the sun vainly tries to shine in through the flour-coated windows far above the city's roofs. It next passes over a wire sieve, which separates the bran from the kernel proper.

This bran, which contains much of the flour material, again passes down and is ground once more, this process being repeated four times, making five grindings, each one finer than the one preceding it.

Each time the fibrous or bran portions are more completely separated, and at last the bran comes out a clear, brownish husk, with every particle of flour removed.

The inside part of the kernel has meanwhile been going through a very interesting process. After the first grinding or breaking, it passes to a big six-sided revolving wheel, covered with a fine wire netting or sieve. Through this reel the finer portions of the kernel pass, coming out in what is called "middlings," a granulated mass, which goes back to the rollers for another crushing.

The process is repeated through five reels, all but the first being of silk. The last one has 120 threads to the lineal inch. The flour which comes out of the fifth reel, while white in hue, is yet not of the finest nor "patent" grade, but is classed as "haker's" or second-grade flour.

The middlings above referred to are purified by an interesting process. They are passed over a fine wire sieve, through the upper part of which a strong current of air is passed. This holds in suspension the tiny portions of fibrous matter which may have been in the flour, and, at last, after this process of middlings purifying has been carefully carried out, the flour appears a spotless, shown white—the "patent" flour, as it is called.

In the process of grinding in this gradual and repeated way the germ of the wheat—a tiny particle about the size of a mustard seed—is separated from the white flour. It is what one might call the life part of the wheat.

If it were ground up it would not leave the "patent" flour so white and powdery, so it is separated in one of the sievings and passes into the darker or lower grade of flour. It contains, however, the best and most nutritious part of the wheat.

The last thing that happens to the pulverized kernel before it is ready for market is the filling of barrels or sacks. Down many stories through a smooth tube comes the white or patent flour. Under the tube is the harrel or sack, as the case may be, and, as it begins to fill, a steel anger just the size of the barrel bores down into the flour, packing it carefully and solidly beneath the broad blades.—St. Nicholas.

ACCORDING to Professor Bemis' figures, based on the census statistics of 1890, the average wages of the 24,323 miners in Illinois were only \$6.87 a week; of the 19,591 Ohio miners, \$6.76; of the 53,780 bituminous miners of Pennsylvania, \$7.55, and of the 70,669 anthracite men, \$6.21. The report for 1892 of the Ohio Bureau of Labor Statis-

tics confirms this, for it gives the average weekly earnings in 1892, in that State, as \$6.67. In most States wages average about \$2 a day when the men have work, but this is not usually over 200 days in the year.

A New Way to Retort Gold.

We recently asked a miner who was getting fine gold by slicing how he saved it. "I use silver," he said, "and squeeze it through calico, and when I have got the amalgam as hard as I can—" "You retort it," we said. "No, I don't and yes I do—I don't as you mean retort, but I do as I mean it myself. I get a potato, cut off one end, and scoop out a cavity in it large enough to take my ball of amalgam. I next take a spade or piece of flat iron, and place that over the fire; and then upon that I place the potato with the cut side down. As the amalgam gets hot the silver evaporates and goes all through the potato; but it can't get through the skin, and neither can it escape by the iron, for the spud is stuck to the spade. When it is done I take the spade off the fire and let it get cool, and then I have my gold in a button on the spade and my silver all in fine globules in the potato. I break that potato up under water and I have all my silver. Many persons don't believe this can be done, but I tell you it can, sir, and I tell you, also, that I don't know how it is but my gold is always of a good color, and I've often wondered if the juices of the potato have anything to do with that."—*Australian Mining Standard*, April 21.

A Curious Puzzle.

Open a book at random and select a word within the first ten lines and within the tenth word from the end of the line. Mark the word. Now double the number of the page and multiply the sum by 5. Then add 20. Then add the number of the line you have selected. Then add 5. Multiply the sum by 10. Add the number of the word in the line. From this subtract 250, and the remainder will indicate in the unit column the number of the word, and in the ten column the number of the line and the remaining figures the number of the page.

The Main Full of Beer.

"The most curious thing I saw in Europe," remarked Wm. M. Hoff, of San Francisco, who has just returned from a tour of the old world, "was the manner in which beer was served at Stuttgart. It is piped all over the city, just like water, and the consumer pays a beer rate, just as he pays water and gas rates. Two immense breweries furnish the supply, and because of their political 'pull' they have monopolized the entire beer trade of that immense city. Their mains make a perfect underground network, with smaller pipes tapping them at distances of twenty to fifty feet. The pipe is made of a lead composition, and to preserve the heverage from impurities which the chemical properties of the beer would generate in contact with the metal, the pipe is lined with a thin layer of wood pulp. This makes it possible for every man in Stuttgart to be his own bartender. All he has to do is to turn the spigot and the pipe does the rest. The pipes, of course, are air tight, so that the amber liquid is as pure and sparkling when drawn in one's home as when taken from a bottle or passed over the bar by a knight of the apron. You can readily see how this system of serving beer cheapens it to the consumer. It does away with an army of middlemen, for every family who patronizes the breweries gets the heverage first hand. This unique experiment has already become an established success in Stuttgart, and is growing in popularity so fast, that every large city in Europe is talking of adopting it."

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, and is also one of the processes for Zinc.

The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

CALIFORNIA.

Calaveras.

LAKE LOCATION.—Ankels Echo: Professor Brooks, who recently bought the Viertong mine, near Tuttle town, Tuolumne county, has bonded the Ferguson-McArdle mine, located on the south bank of the Stanislaus river. The north boundary of this mine is located near Wood's Ferry, on the Tuolumne side, running thence south 12,500 feet along the main road to Sonora. He has also obtained a bond on the Brown mine, owned by Boye and Miner. This means a large property for a solid company, as it is a well-established fact that gold exists in large quantities in Jackson Hill, which forms a portion of this immense mine.

MANUFACTURED COPPER.—Echo: We have been handed a specimen of copper manufactured at Copperopolis by electricity, or by what is known as the new system of producing that article. The specimen shown us was produced in something less than six hours and is about the sixteenth of an inch thick. If gold could be produced by a like process it would knock out the gold bugs of Wall street in a jiffy.

Del Norte.

AFTER A BIO MONEY.—Speaking of the revival of gold-mining in the State, the *Crescent City Record* expresses the opinion that before long the unexplored sections of Del Norte will receive a thorough prospecting. "It is well known," says that paper, "that in early days the country was prospected, but the men who went over the ground were in search of big money and washed a pan of dirt here and there." It appears that, though since that time quartz leads have been discovered all through the mountains to within a short distance of Crescent City, very little prospecting and no real development work has been done. The *Record* doubts whether there is another county on the coast with a greater variety of minerals than Del Norte.

Inyo.

RANCHO CANYON.—Register: The Georgia mine, owned by Geo. F. Willis and others, is being worked at depth, and shows a good grade of ore. The last five tons extracted will probably mill \$50 per ton.

N. W. Willis is getting some very good ore. The report has been widely circulated that the "gold does not go down in the Inyo mountains," and that one can hope for nothing but surface "prospects." However, the results so far as can be known from the deepest workings here (about 200 feet) seem to prove the contrary.

Geo. Story has just finished an arrastra, and will soon start up on ore. He has a Pelton motor for power. His arrastra is about three-fourths of a mile below the one owned by Geo. F. Willis. The owners of the Georgia will furnish a run of 25 tons of rock in a few days that promises to excel in richness anything that has been run from that mine as yet. There will be considerable custom rock run at the Willis arrastra this summer.

FINE MARBLE.—Independent: Recently two carloads of very choice marble were sent out from the Inyo quarry. The blocks weighed about ten tons each. There are orders now on file for marble that will keep the mill running day and night for the next six months to come. Mr. Holmes, superintendent, has lately opened up an immense body of marble different from any yet found there. He says the ledge is over a mile long and a hundred feet wide. Mr. Holmes says he could take out blocks twice the length of the Washington monument "and without a flaw."

Mono.

WEEKLY LETTERS.—Supt. Kelly's official letters for week ending June 3d are as follows: Bodie.—During the past week north drift from No. 1 west crosscut, 300-foot level, was extended 10 feet. The face is broken up, but the bunches of ore through the porphyry are good grade. Winze from above drift was extended 8 feet. The ore in bottom is about 12 inches wide and good grade. Commenced crushing ore in the Bodie mill on the 30th of May; crushed 71 tons; average battery sample, \$37.08; average tailings, \$9.38. There were employed six miners, one engineer, one carman, one carpenter and, jointly with Mono, one engineer, one blacksmith, one watchman, one foreman. Mono.—During the past week we cleaned out and timbered No. 1 east crosscut from main south drift, 550-foot level, a distance of 60 feet. There were employed two miners and, jointly with Bodie, one engineer, one blacksmith, one watchman, one foreman.

Nevada.

CHANGE OF OWNERSHIP.—Union: The Osborn Hill mine is now owned by the company that has been operating it for the past 18 months under a bond. Yesterday the balance due on the purchase price, amounting to \$30,000, was paid to Messrs. Robert Smith and William Campbell and Mrs. John L. Smith. The Phoenix mine was bought by the Osborn Hill Company last Monday for \$60,000. It was owned by Edward and John C. Coleman, Wm. Campbell, John Glasson, A. Burrows, George Campbell and Mrs. Mary J. Neelis. It adjoins the Osborn Hill mine.

Siskiyou.

MINING NOTES.—Journal: Austin & Co. still continue to take out good pay from their claim at Greenhorn, about a mile south of Yreka, with prospects of improvement as the claim is opened to better advantage. They realize steadily from \$800 to \$900 of gold dust per week, and employ about 20 hands. Newt. Lamb, who has commenced opening a

claim farther up the creek, has the pumping machinery in operation, and will soon commence tunneling along the bedrock from the pumping and hoisting shaft.

Plumas.

J. P. Welsh of this city has bonded the Glazier mine at North Fork and will work it with a force of men. Mandeville and Rickard have a ledge the croppings of which show free gold, and which they will develop this summer. It is the general belief that rich gravel exists deep down a hundred feet or more below the surface, not only on Greenhorn, but in many other sections of Yreka basin.

At Salmon river, the miners are all very busily engaged with an abundance of water, and expect to take out more gold this season than ever before. The hills and gulches are full of industrious prospectors, and more are coming every day to try their luck in that extensive mining region, where gold can be found in the gulches, creek and river beds and mountains both in quartz and gravel. The mountains are still covered with a great amount of snow to keep the small streams and ditches supplied with water for mining purposes until the winter season is again upon us to renew the supply.

Tuolumne.

Independent: The Buchanan mine directors have levied an assessment. We hope that this is an indication that the grand old mine will soon resume operations to purge the yellow metal still pressing its plethoric stomach.

The Dead Horse mine suspended operations at its mill last week. The superintendent, Capt. Thomas, will for a time prospect at the 1300-foot level in the hope of getting better payable ore. The main shaft is sunk 1340 feet, and at this depth thousands of tons of ore are available, but it is not as rich as the company desires, hence the above operations.

The late rains and fall of snow in the mountains will extend the mining season next fall for those who depend on a water supply. The present prospects are encouraging for a long and profitable mining harvest.

NEVADA.

Washoe District.

ORE FROM THE CON. VA.—Enterprise: The first shipment of ore from the Con. Virginia mine to the Morgan mill was made Sunday. The ore was taken from the new bonanza on the 1650 level some time ago, and has been held in bins at the mine. Returns from the ore will be awaited with great interest.

The work of pushing the 1700 foot drift toward a point beneath the ore find on the 1650 level, has been progressing rapidly, and the objective region will be reached to-morrow. The drift continues in low-grade quartz.

EXCITEMENT AT KENNEDY.—Walker Lake Bulletin: The excitement over the rich strikes in Kennedy is increasing every day. All who visit the camp agree that it more than equals any former discovery in the State, some not even excepting the Comstock.

There have been over 400 locations made, and all that work has been done on show good healthy ledges that assay well in gold—some very high, but all good enough, with a mill near by, to work at a handsome profit. The Imperial, which was purchased by Mr. Wardner, has over 4000 tons of \$30. ore uncovered that can be taken out in short order and milled at very slight expense, and the chances are that by the time that is taken out he will have as much more uncovered, as he intends pushing the tunnels right in, and from the croppings it looks as if the ledge extends the whole distance of 4300 feet that he owns.

ARIZONA.

GENERAL NOTES.—Journal-Miner: The Socorro smelter has sent notices to its patrons announcing that it will close on June 15. Many of the smelters have been running at a loss, and it is not unlikely that others will follow the example of the Socorro one.

The mill owned by Messrs. Rucker & Morse on Lynx creek is running right along with good success. This district has resumed its old-time activity again and gives great promise for the future.

Major W. A. Rowe is still at work on the Shelton group of mines in the Lynx Creek district, and he reports the property looking splendid. He has recently struck a very large chute of good gold ore on one of the claims in a new shaft which he is sinking.

John S. Jones is sinking a well on Big Bug, with excellent prospects of obtaining a water supply, which, added to what he has at present, will enable him to run his mill the entire year. He proposes to sink fifty feet and then crosscut across the creek.

A large body of very rich ore was struck in the Railroad mine, in the Hassayampa district, which is being worked under lease by Messrs. Fisher & Wood. The ore was struck in the winze which is being sunk in the upper tunnel of the claim.

Water is reported becoming very scarce in Martinez creek, from which the Congress obtains its supply for its mill. The Congress managers have been drifting under the creek, on bedrock, for the purpose of increasing the supply, and have partially succeeded, but the outlook is not encouraging and the mill may have to be closed down yet this month for lack of water.

Sam Hill, who recently took a party of mining men into Tonto Basin, reports that district as being quite active. Two mills are running in the district. J. I. Coleman's mill is running on custom ore, while the Lackawanna is running on ore from the mine of the same name. William Murphy is developing a claim owned by him and Dennis Burke. The Zulu is idle at present.

A \$10,000 bar of bullion was brought in last evening from the Crowned King mine and was

shipped to-day to be worked up into coin of the realm. This mine is a bullion producer, but just at present the water supply is getting somewhat scarce, and the mill cannot be run on full time. During the time that they were saving the above-mentioned bar of bullion, several thousand dollars worth of concentrates were saved and shipped, while a part of the ore is rich enough for shipment without milling.

Just as Jacob Henkle and D. F. Mitchell succeeded in opening up their Rapid Transit silver mine, in the Bradshaw mountains, to an extent that it could be placed among the dividend-payers, silver took a tumble, and they have been compelled to let it lie idle until the grasp of the gold monopolists is released from the throat of the silver industry. While the Rapid Transit lies idle, the enterprising ex-sheriff of Yavapai county has not been idle, but has secured a good gold claim in Lynx Creek district and is engaged in working it energetically. He has good prospects of retrieving from this property what he spent on his silver mine.

THE JUMBO.—Kingman Miner: The main shaft of the Jumbo mine, at Rustler, is now down 50 feet, and still going down. The ore shows up nicely all the way down, with the exception of a slight break at a depth of 20 feet. The three-foot ledge will mill \$60 just as it is taken from the shaft, while much of it can be assayed to 15 to 18 ounces in gold. The ore is perfectly free, and as soon as the mine has been exploited to a depth of 150 feet a mill will be erected on the river for the reduction of its ores.

RICH OAS.—"Chas. Sherman's Distaff mine, at Chloride, in Mohave county," says the *Miner*, "turns out some of the richest ore in the country. It is developed by several thousand feet of tunnels, shafts, winzes and raises. Something like \$150,000 has been taken from the property since it was first worked, and it is still, in spite of the low price of silver, being worked for its rich ores. The main shaft, where the hoisting works are erected, is down 225 feet. The shaft is double compartment and is timbered with square sets."

The *Gazette* reports a rich quicksilver discovery in the vicinity of Hassayampa canyon, 60 miles northeast of Phoenix, by J. Goodin. The ore bears all the appearance of very rich cinabar, yet at the same time contains both gold and lead. By the simplest tests Mr. Goodin has extracted mercury from the ore and in extraordinary quantity. He has about 12 feet of the ore, in strong ledge formation.

JOURNAL-MINER: An important placer mining enterprise is assuming shape in the Black Canyon country. The promoter of it is W. D. Church. About 3000 acres of rich placer ground has been located there, and it is said that it will be worked on an extensive scale.

COLORADO.

THE SAN JUAN COUNTRY.—Record: A stream of prospectors, miners and capitalists is pouring into Bear creek over in the San Juan country. The camp promises to be one of the biggest gold and silver districts in the State. Moss-covered rock will pay to ship, indicating that the pay streak outcrops to the surface.

Wm. Bemrose has opened up thousands of tons of gold ore on his Hoosier gulch placer with 400 feet of work, says the *Summit Co. Journal*. The extent of the vein is not known. Two men extracted 3000 tons of ore the last winter and did not use any powder.

A BIO LAWSUIT.—A great lawsuit is liable to arise as to the ownership of the Kansas and Burroughs ore veins, now estimated in value at \$250 per foot or \$2,150,000 for the 10,000 feet included in the claims of both companies. The difficulty arises in this way: The two veins form the sides of an elliptical "horse," of irregular outline, for a distance of some 2500 feet. The lines come together at the ends of this "horse," remain so for a time and then depart in different directions. Where the "horse" prevails each vein dips toward the other, so that as depth is gained they must come together, to so remain or again depart. Development alone can demonstrate this.

When the veins come together below, who will own the ore, the proprietors of the Burroughs vein or the proprietors of the Kansas? One of these companies claims the oldest location, the other claims the apex of the common vein, if it is common in the sense of being one and the same, and separated for a distance by the intrusion of non-mineral matter called a "horse." The apex law was passed by Congress in 1866, at the instance of Delegate Chaffee, and prior to that time, location took precedence in the Gilpin county camps. As both of the veins were worked before 1866, it can easily be guessed that a great deal of ancient history will be unearthed should the rumored suit be brought in the courts.

The *News* thinks that the sensible way out of the difficulty should the veins come together below, as they now threaten, is to consolidate all interests into one company. Millions have been taken from the Kansas and Burroughs, without decreasing in the least the millions more in sight. It is very rich ground.

The territory which separates the two mines, called a geological "horse," was located and patented by J. B. Keeler as early as 1879, under three several titles—the Jay Gould, Welcome and Chicago. There is a shaft on each of these mines and in all of them ore has been found. This disturbs the "horse" theory, as that title is applied to barren ground surrounded by ore veins, like a long peanut in a piece of candy. Four years ago good ore was being extracted from the Welcome.

IDAHO.

TRADA DOLLAR.—Avalanche: About 60 men are employed at the mine and mill. Considerable development work is being done outside of the regular mining operations necessary to keep the mill running steadily. Two drifts

are being extended into the Four ground—the adit or Blaine tunnel and No. 3. The face of the adit is in fine ore, the pay being from two to three feet in width. Most of this ore is stripped and left standing on the footwall. Within the past few days the face of No. 3, which has been full of quartz stringers, has made a nice streak of ore, and is looking very favorable. In the numerous stopes, and in the drifts from the upraise, work is progressing favorably and some very rich rock is being extracted.

GIBBONSVILLE DISTRICT.—A Butte correspondent writing from there says: There has been a great revival in the mining industry in the Barclay section of our camp. The people are far more hopeful for the future of Gibbonsville than for a long time past. The operations of the American Developing and Mining Company have put new life in the camp. Their mill is running full time on ore recently bought of Hubbs, Barton & McMahon, at their lower tunnel, which is being run to open all their back leads. They have a force of men excavating for the foundation of an air-compressor, which is to be placed at the mouth of the tunnel for the purpose of supplying compressed air for the Burley or Ingersoll drills which are to be used in extending this tunnel, which is now in 1500 feet; also for the ventilation of the mine.

NORTH SIDE MINING IRMS.—Coeur d'Alene Sun: There are 11 men employed by the Nugget Company—four on the night shift and seven on the day shift. A great deal of gravel is being washed.

Five hundred pounds of powder were fired off by the Arizona Placer Company on Friday on Gold Run. It raised the 60-foot gravel bank several feet and left it an easy prey for the magnificent water power of the company.

The Vestal Con. Company fired off a 250-pound powder charge during the week, and broke down an immense amount of gravel.

The lumber for the new Daddy quartz mill will be sawed during the coming week. The mill is expected to make industrial music on the 4th of July.

George Ives has had a force of men at work cleaning out the Missoula ditch for an increased supply of water in Dream Gulch. The work is about finished.

MEXICO.

SHIPPED TO ENGLAND.—Vidette: Another bullion producer has been added to the mines of Sonora. The mine is located just across the line, a few miles from Bisbee, in the Cananea mountains, and runs heavily in copper. The quantity of ore is large and there will be three furnaces in operation by the middle of this month. The product is shipped in bond to England, the first lot going this week, which is expected to be followed by numerous heavy shipments. John Weir is the representative of the company.

MONTANA.

A BIO MINING SUIT.—Inter-Mountain: Howard H. Zenor of Deer Lodge, one of the original locators of the Comanche mine, has brought suit against P. A. Largey for the annulment and cancellation of a deed conveying to Mr. Largey a one-fourth interest in the Comanche. The plaintiff alleges that on October 11, 1883, he was the owner of and in possession of a half interest in this property, and that the defendant by force and fraud and misrepresentation, and by threats and intimidation against the plaintiff and without consideration to him compelled him to make and execute and deliver to the defendant a bargain and sale deed conveying to him a quarter interest in the said claim. This deed the defendant recorded. In September, 1893, the plaintiff alleges he was made aware of the fraud and misrepresentation whereby the defendant had obtained the deed and a demand was made that the property be reconveyed to him. The value of the fourth interest is \$50,000.

MINING NOTES.—Inter-Mountain: Stacey & Dickey of Rochester shipped a car of gold ore to Butte this week that went \$100 to the ton.

J. H. Vanderheck of Virginia City shipped a car that averaged 75 ounces in silver and \$60 in gold per ton.

A shipment of 50 tons of manganese ore was made from the Mono mine, one of the Blue Bird Company's claims.

Bennett & Clark, leasing the Goldsmith No. 2, shipped 50 tons of ore during the week, that went 150 ounces in silver and \$30 in gold to the ton.

The Golden Sunlight Company has not yet let the contract for the proposed 150-ton concentrator, but it is expected to be let during the coming week.

The Basin Times reports that a rich strike has been made in the Lone Star mine, owned by Samuel Mulville. It is being worked under lease by L. A. Sisley and others, who have it bonded for the sum of \$50,000.

A force of about 40 men is engaged in building a concentrator on the Katie mine at Basin. Mike O'Donnell has been paid \$20,000 cash of the \$30,000 due him for a one-third interest in the mine. The balance is payable in October.

Fine & Pankey started up their Bryan mill last week. This is an annex to the regular mill. It receives the tailings from the vanners. The tailings are pressed dry, then roasted, and after being thoroughly chloridized are worked through pans and settlers.

Col. Johnson is back to his old stamping ground on Richmond Flats from North Carolina. It was Col. Johnson who sold the Revenue mine for \$180,000 six years ago. About 30 days ago he returned and immediately started work on a mine next to the Revenue, and during the week made a shipment of one carload.

NEW MEXICO.

MOOOLIONS.—Silver City Enterprise: Forty carpenters are employed on the new Confidence

mill on Whitewater, and every nerve is being strained to have the mill ready for operation by September 1st. The road will soon be ready for hauling ore over, and then the thousands of tons of ore on the dump at the mine will be taken to the mill. After the ore is removed from the dumps at the mine, ore bins will be put in place, which will facilitate the loading of ore. As soon as these bins are in place work will be resumed on the mine under the superintendence of John T. Mitchell.

WHITE SIGNAL.—This camp is situated on the eastern slope of the Bnro range of mountains. The center of operations is in the neighborhood of Donaldson's pump station. Recently, however, in the great rush for gold, attention has been attracted to these mines. The geological structure of the veins bears a strong resemblance to many of the Mogollon series. A large body of conglomerate quartzite runs through the district from north to south for a distance of 10 or 15 miles. On either side of this quartzite, porphyritic felsyte, rhyolite and other porphyritic rocks predominate, with occasional bodies of leptonite or metamorphic granite, all of which are heavily impregnated with iron, so much so that the dark oxides of this mineral give the massive rocks a somber hue. From both sides of the great band of quartzite before mentioned, several series of porphyry dykes seem to project at various angles. These rifts or dykes of porphyry are from 8 to 40 feet in thickness and traceable from a few hundred yards to a mile in length away from the quartzite. On one side of these porphyry dykes, and in many instances on both sides, and in immediate contact therewith, are found gold-bearing veins. So far there have been discovered and located somewhere in the neighborhood of 60 claims. The veins vary in width from six inches to three feet, and in value from \$8 to \$20 per ton in gold.

REPORTED STRIKES.—*Enterprise.* Messrs. Kline, Marty and Professor Miles are working a gold property in the south end of the Bnro mountains. The vein is from 6 to 40 feet in width and assays from \$8 to \$20 per ton in gold. They intend to sink to a depth of 100 feet and then arrange for reduction works to mill their ore.

A strike of rich gold ore has been made at the southeast end of the White Signal camp near Thwaite's ranch. The ore assays from \$10 to \$200 per ton and is found disseminated through an immense mass of quartzite all of which will pay so far as developed.

On the Texas mine sinking has been resumed from the 200-foot level. In the bottom of the shaft very rich ore has been encountered; the ore will run \$50 per ton in gold and 200 to 400 ounces per ton in silver.

COCHITI DISTRICT.—*Record.* New strikes of ore running from \$32 to \$100 per ton are so frequent in the Cochiti district that they excite very little comment. Returns just at hand from Burlingame show \$700 ore in a new prospect in Cella canyon. In the Lone Star tunnel a rich vein of \$400 ore has been struck, and when roasted it shows blisters of gold. That the principal mines run high in tellurium is now settled beyond all doubt. A fine body of mineral similar to that in the Crown Point, has been uncovered in the Miners' Union claim in the west fork of Pino canyon, over a mile from the Crown Point. In Cochiti canyon the Little Colorado claim, owned by La Junta parties, reports a new strike, assay returns from which have come to hand from Pueblo. It yields \$41 in gold and \$35 in silver, making a total of \$126 to the ton. Near Bear canyon, ten miles south of Pino canyon, some fine ore is being extracted, and the ledges are similar to those in the Lone Star. One claim, which shows 12 feet of quartz, gives an assay return of 1 ounce in gold and 3 3/4 ounces in silver. The same croppings are found near Borego Springs, and things are lively in that locality.

A LITTLE CALCULATION.—*Socorro Chief.* To run a five-stamp battery it takes 15 tons of ore per day. Each ton of common quartz ore has about 20 to 22 cubic feet in it. At 30 days in a month, for six months, it would take 2700 tons of ore, or 54,000 cubic feet of ore, to keep the stamps running. The Wall Street, of Water canyon, is doing this, and could keep ten stamps running for some time. Talk is cheap, but it takes money to buy saw-logs, and lots of ore to run a mill. And when other places are doing their booming, remember that the Wall Street, in Water canyon is doing this.

OREGON.

SOUTHERN OREGON PLACER MINES.—Considerable interest is caused in the vicinity of Medford by the result of a partial cleanup of the Miller placer mine, situated about five miles west of that city. The mine was recently purchased by Portland parties, and between \$12,000 and \$13,000 has been taken out as the result of the past run. A partial cleanup of the Sturgis mine, about 12 miles from this city, which was finished last week, produced \$30,000 in yellow metal for its owners. These mines are considered two of the best placer mines in southern Oregon, and the result of the cleanup of both has been watched with interest by mining men all over the State. The Miller mine comprises about 240 acres, all of which is considered as good as that worked in the past, only two acres of which has been touched during the last eight years. The mine has been run with only one giant, and the present company is making arrangements to put in two more giants.

BULLION FROM CORNUCOPIA.—*Baker City Democrat.* About 100 pounds of bullion in bricks was on exhibition at the First National Bank of Union Saturday. It was sent in by Mr. Fred Steen from Cornucopia, and is the result of his work upon the tailings from the mill of the Oregon Gold Mining Company. The bullion

was principally silver, although it contained some gold.

UTAH.

S. L. Herald: The Bullion-Buck people at Enreka are employing over a hundred men and shipping a great deal of high-grade ore, and have from 70 to 100 tons of low-grade ores on the dump that will be of great value to the company when they get a mill erected for treating them. At present they are not worth shipping. The company is preparing to put in a mill, at an outlay of from \$50,000 to \$60,000, for the treating of their low-grade ores. On the 2d inst. the company paid a \$50,000 monthly dividend, or 50 cents per share on the capital stock of the company.

Bingham Bulletin: The Stewart mill is a sight worth seeing. As to its perfect work, the many gold bricks—ranging in value from \$500 to \$18,000 each—which it has been turning out during the past year are sufficient proof. The five Huntington mills are kept in constant operation, and from 50 to 60 tons of ore is being put through daily.

THE LITTLE PITTSBURGH.—*Record.* An important discovery has been made in the Little Pittsburgh group, situated in the northern part of the Mercer district, over in Utah. Milling ore in a vein 25 feet thick, and no foot wall yet, is the claim made by the operators and those who have visited the workings. Assays show the value to be from \$6 to \$7 per ton, and picked samples give returns as high as \$23.

WASHINGTON.

GOLD MINING AT WENATCHEE.—*Report.* D. E. Bigelow, manager of the Wenatchee Gold Mining Company, gives an encouraging report of his property, which is located about two miles from the town of Wenatchee. The company has a five-stamp mill in operation. The ore, of which they have a great supply, is a partially decomposed quartz and carries sufficient gold to insure handsome profits from the running of the mill. The ledge crops out for two miles and the ore is easily taken out. The mine is so accessible that the delivery wagons from the Wenatchee stores drive up to the works. Mr. Bigelow thinks they have an inexhaustible supply of ore to run on and is sure that the property will in the near future be one of the large gold producers of the State.

Coast Industrial Notes.

—The Edison Light & Power Company yesterday paid its monthly dividend of 66 2/3 cents per share.

—The sealing fleet report a very large catch. So far four vessels have been lost, and six are missing.

—The California Electric Light Company paid its monthly dividend of fifteen cents per share yesterday.

—The Canadian Pacific will build a new steel bridge over the Columbia River at Revelstoke, B. C., this summer.

—From five to ten dollars a day were the recent ruling wages for fighting the flood and saving property in Portland, Or.

—A large grain warehouse and elevator is to be built at North Seattle, Wash. The company is to be capitalized at \$300,000 to \$350,000.

—British Columbia mill men are buying logs in Washington and towing them to their mills. Just a year ago precisely the opposite condition of affairs existed.

—Dodge, Sweeney & Co. have bought the Alaska Packers' Association's salmon pack of '94 in barrels and half barrels at \$6 for barrels and \$3.50 for halves. This is \$2 lower than '93.

—The Potrero & Bay View Railroad Company has filed articles of Incorporation, to build a road from Post and Montgomery streets, San Francisco, to the Bay View race-course, or to Hunter's Point.

—The separation of the Oregon Railway & Navigation properties from the Union Pacific system under a separate receivership had been arranged to take place to-day, but the damage of the great flood has compelled indefinite postponement.

—The twenty-second payment to the Union Iron Works on account of the construction of the Oregon, amounting to \$96,684, has been deferred until the naval appropriation bill passes, as there are no funds available for this purpose.

—The Union Iron Works in May sent a complete sixty-stamp mill to the Apollo mine, Ungra Island, Alaska. They also furnished a twenty-stamp mill to the Osborne Hill, at Grass Valley, and sent a ten-stamp combination process mill to Weber, Idaho.

—R. B. Langdon & Co. of Minneapolis have secured a \$2,000,000 canal contract in Arizona. The country to be irrigated is 400,000 acres, mostly in Maricopa county, and the water to be obtained is from the Rio Verde. The canal will start above Phoenix and be 100 miles long.

—Work on the new reservoir for the Paso Robles Water Company has commenced. It is to be built east of town in the Callender tract. The capacity will be 1,200,000 gallons and the cost \$6000. New ditches are to be dug, new pipes laid and new mains put

in, and the whole cost is estimated at \$15,000.

—The annual statement of the Pacific Mail Steamship Company for the year ended April 30 shows a balance of receipts over expenses of \$475,461. There was a deficit last year of \$56,740. The statement is reiterated in some quarters that the company is in financial stress and about to pass into the hands of a receiver.

—The local trade in concentrators is good. The Risdon Iron Works have an additional order for thirteen from the Apollo Consolidated Mining Company. George E. Woodbury has recently sent twelve to Colorado, three to Australia and three to Oregon. The McGlew Company report six sent to Grub Gulch and two to Nevada.

—The Union Gas Engine Company of 221 First street are finishing the construction of a seventy-horse-power gasoline marine engine for J. S. Kimball, the lumber man, to be used on a lumber coasting vessel, believed to be the largest gasoline engine ever built on the coast. They built a fifty-horse-power engine for Mr. Kimball last year.

—The Redlands Electric Light and Power Company are investigating the merits of a new electric car system of which a sample is in operation in New York. The system does away with the trolley, the current being carried through a metal strip in the center of the track. By a system of switches, none of the strip is charged with electricity at any time except that directly beneath the car.

—Major Post has taken charge of the fight to save the Cascade locks, on the Middle Columbia river, the Government standing the expense. Six trains are running, hauling brush, gravel, rock and anything that can be utilized to raise the bulkhead. Some of the cut stones are being dumped into the works, and seventy barrels of cement were used in one day in solidifying the sand and gravel.

—Talking of the much-discussed San Joaquin Valley Railroad, Traffic Manager Leeds says: "I have found no difficulty in interesting people in behalf of a scheme appeals to the financial interests of all. The cost of the road will not be over \$10,000 a mile. The matter is being considered daily in the executive committee of the association, but no steps have been taken so far to incorporate a company. This will be done shortly."

—Plans are being perfected for the reclamation by the State of nearly 1,000,000 acres of swamp and overflow lands on the Sacramento, Feather and San Joaquin rivers and their tributaries. Nearly \$15,000,000 has heretofore been almost wholly wasted in a similar effort. The plan in general will be to utilize the waterflow for dredging and create a system of reservoirs. The matter will be embodied in an engineer's report to the Legislature.

—The local market is unusually bare of Australian gas and steam coal, and cargoes to arrive are quoted at full figures. The business at the Tacoma coal mines is reported good at the present time, considering the general depression of trade. The Carbonado mines, which ship their product to the Southern Pacific Railroad Company here, send 30,000 tons monthly. The Wilkeson mines produce from 11,000 to 12,000 tons monthly, and convert a large amount into coke in their ovens at the mines.

—The result of the recent test of Washington coal made by the several vessels of the Behring Sea fleet is waited for with considerable interest. For years every effort has been put forth to induce the naval authorities to buy American coal instead of the coal from the British Columbia mines. The contract for this year's supply was made as usual with the Comox mine on Vancouver Island, but Secretary Herbert afterward ordered the Behring Sea fleet to visit Puget Sound and make a thorough trial of the steaming qualities of the Washington product.

—The Pacific Steam Whaling Company's steamer Jennie has started for Herschel Island, in the Arctic Ocean, with a cargo of supplies for relief stations that have been established for distressed whalers and sealers and stores for the crews of the whalers that will go into winter quarters at Herschel Island when the ice begins to pack. Among the cargo are 150 cases of coal oil, 700 tons of coal, 530 barrels of beef, pork, fish, etc., 837 cases of canned meat, fruit and vegetables, 10,000 pounds of beans, 11,000 pounds of bread, 17 barrels of beer, 1100 pounds of dried fruit, 5500 pounds of coffee, 350 barrels of flour, 15,000 pounds of sugar, 49 barrels of molasses, 3 barrels of rum, 7 cases of whiskey and 2000 pounds of tobacco. She carries 4 whaleboats, 25 cases of rifles and 25,000 cartridges.

Patents Issued to Pacific Coast Inventors.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order. American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC UNCOUPLER AND CAR BRAKE.—Joseph P. Dias, S. F. No. 520,204. Dated May 22, 1894. This invention relates to an attachment for cars which is designed to automatically uncouple the cars when any accident happens by which the car in front becomes derailed or thrown down, and to simultaneously apply a brake to the cars remaining upon the track. It consists of a device adapted to be operated by a downward pull of the forward car; a longitudinally-moving head, connected with a coupling link so as to be drawn forward with it when the cars are separated; a brake shoe suspended in front of the car wheels, with a supplemental grip shoe slidable on it and adapted to move down upon the point between the wheel and the track; a bell crank lever and a connection between which and the movable shoe and a rod connecting the bell crank lever with the movable part of the coupling. There is a stationary pin upon the car, and a spring which retains the link in place when it is connected with the pin, this spring yielding to allow the link to be tilted downward and disengaged. There is also a pawl and ratchet mechanism by which the bar is retained in the advanced position after it has been drawn forward and the disengaging piece which allows the coupling chain and link to be dragged away if the front car is disengaged without disturbing the othercar.

ELECTRIC ADVERTISING OR SIGNALING APPARATUS.—No. 520,223. May 22, 1894. George L. Schneider, San Francisco, Cal., assignor of seven-eighths to Wm. J. Pattosien, Fred L. Waibel, Charles Fisher, George Brandt, Gus A. Paul, Fred Brandt and A. R. Paul of San Francisco. This invention relates to the class of devices adapted to electrically produce visible signals. It consists of a mat or frame of electric lights, a correspondingly arranged series of contacts with electrical connections with such lights, a series of push buttons adapted to make and break electrical connection with said contact, and suitable electric circuits including these parts. The series of contacts may be remote from the mat or frame containing the lights, and is electrically connected with the lights, and these contacts correspond in number and relative position with the positions of the lights, so that a metal plate fitted over the contacts with a series of spring-actuated push buttons in the plate, normally out of electrical connection with the contacts, is adapted to make and break the connection. A single circuit wire includes the plate, button, contact and lights in its circuit.

STEP LADDER.—Julius E. Chittenden, Niles, Cal. No. 520,202. Dated May 22, 1894. The object of this invention is to provide an improvement in step ladders which allows them to be used in either outdoor or orchard work, and to provide simple adjustments by which the relative position of the feet and supports may be regulated and the width of the base altered to suit the position and height of the ladder. It consists of a main portion composed of sides and steps having a supplemental exterior frame comprising sides converging from points opposite the lower end of the main portion of the ladder and extending to a distance above the upper portion, converging to a point at the upper end. Transverse strips unite the two parts and hold them together, and an expandable base formed of diverging legs serves to increase and regulate the width of the base to suit the surface or position of the ladder. The rear portion of the ladder is supported by a single adjustable leg having sliding parts, means for holding it in any of the various positions in which it may be placed, so that the ladder may be readily adjusted to stand upon any uneven surface.

TRACK OR CARRIER FOR DOORS.—George E. Witt, Fresno, Cal. No. 520,199. Dated May 22, 1894. This invention relates to a device for suspending sliding or travelling doors or carriers and for other similar purposes. The object of the invention is to provide a device for suspending any traveler which is intended to run from one point to another. It is applicable to the suspension of car and other sliding doors, also for transporting hay in barns and for other similar purposes. It consists of a suspended traveler having hangers provided with rollers, a tube having its lower surface slotted to admit the hangers so that the rollers travel within the tube, and the tube itself is journaled so that it may turn about its longitudinal axis, so that if desired the doors may be turned up and supported in an

approximately horizontal position to form an awning. The hangers have openings of sufficient diameter to allow the rollers to be introduced from the side, and a slot connecting with the upper part of this opening serves to receive the axis which extends between the rollers, the rollers being separated a width equal to the thickness of the hanger. One of the supporting brackets is also slotted to correspond with the slot in the tube, and by removing an end cap upon the tube, the hangers may be moved out through the slot in the bracket so as to be entirely removed from the tube, the door thus being taken off or replaced at will.

CONCENTRATOR.—A. H. Rapp, San Francisco, Cal. No. 520,939. Dated June 5, 1894. This invention is intended to provide an improvement to apparatus for the separation of valuable or heavy material from the lighter sands, earth and tailings with which it is mixed. These substances are very difficult to separate, and it is the object of this invention to assist in the separation. It consists of a sluice having transversely movable agitating plates, the lower portions of which dip into the passing current and are twisted so as to present flat surfaces to obstruct the flow of the current. It also consists to means for reciprocating these plates horizontally, a means for varying the angle or position of the plates, and in conjunction with this device of transverse rifles across the bottom of the sluice having under cuts and intermediate pockets into which the heavier material will settle and lie out of the path of the current flowing through the sluice.

SULKY BRAKE.—Leonard E. Clawson and J. A. McKerrow, San Francisco, Cal. No. 520,877. Dated June 5, 1894. The object of this invention is to provide an automatically operating attachment whereby the wheels of sulky or other two-wheeled vehicle may be instantly locked whenever the horse attempts to rear, and thus to prevent the vehicle from running under the horse and throwing him over backward. It consists of an arm connected with the vehicle at a point eccentric to the wheel center, extending downwardly so that it will stand normally out of contact with the ground, and a lever upon the lower portion of said arm provided with a brake surface adapted to be thrown into contact with the wheel when the frame is raised to force the lever into contact with the ground.

338; fractional silver coin, \$17,582,973; silver bullion, \$127,231,644. On May 31, '93, the total was \$29,160,279 less than on the 31st ult.

Mining Share Market.

It has been a dull week in the mining share market. The exchanges will have a holiday from June 29 to July 5. The decline in the early part of the week was not followed by a very active movement, and the aggregate of sales was small. The following illustrates the changes of the week:

MINES.	7	14
Utah	\$ 6	81 85
Sierra Nevada	68	67

There is announced a total in June on mine assessments of \$167,480. Of this amount, Storey Co., Nev., represents \$120,230; three counties in Cal., Inyo, Nevada and Mono, call for \$27,250, and Pinal county in Arizona, \$20,000. Completeness is not claimed for this or any similar summary, but as in other summaries it is full so far as the publicity given to the details from which it is gathered make it possible.

Assessment Notices.

OCCIDENTAL CON. MINING COMPANY—LOCATION of principal place of business, San Francisco, California; location of works, Silver Star Mining District, Storey County, Nevada.
Notice is hereby given that at a meeting of the Board of Trustees, held on the thirty-first day of May, 1894, an assessment (No. 18) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the fifth day of July, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the thirty-first day of July, 1894, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Trustees.
ALFRED K. DUBROW, Secretary.
Office—Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from L. V. Pettit in the Concordia mine, near Cromberg, Plumas County, to deposit tailings behind dams in Osgood Ravine and Jackson Creek; from the Northern Placer Mining Company in their mine near Cromberg, Plumas County, to deposit tailings behind brush dams in Little Long Vale Creek; and from Thomas White in the Schuyler mine, near Igou, Shasta County, to deposit tailings behind dams in Dr Creek, give notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on June 26th, 1894, at 1:30 P. M.

THE RUSSELL PROCESS.

For information concerning this process for the reduction of Ores containing precious metals, and terms of license, apply to
THE RUSSELL PROCESS CO.,
Park City, Utah.

Market Reports.

The Markets.

SAN FRANCISCO, June 14, 1894.

After a few fluctuations the price of silver closed the same as for the corresponding period of last week. The see-saw since Jan. 1 leaves little difference to note. The highest reached in January was 31 3/4 d in London; 69 cents in New York; the lowest was in May, 28 d in London, 61 cents in New York. During the first five months of 1893 the highest was 38 3/4 d in London, 84 1/2 cents in New York; the lowest, 37 1/4 d in London, 81 1/2 cents in New York.

A good investment for big sums would seem to be the purchase of silver at present prices. It is sure to appreciate, with resultant effect upon large purchasers, making them rich beyond the dream of avarice.

New York Prices.

NEW YORK, June 14.—Following are the closing prices for the week:

Silver in—	Copper.	Lead.	Tin.
Thursday.....28 3/4	62 1/2	9 25	3 20 19 50

213 FIRST ST., SAN FRANCISCO, CAL.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED
Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE,
Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE COMPANY'S WORKS, 180 MAIN STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW ORE CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing OLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

Universal Milling Machine.

Herewith is illustrated a universal milling machine, the table of which can be swiveled to any angle.

The feed has four changes, and is tripped automatically, or by hand, under full cut, as easily as when the table is running light. A full range of spirals, right and left hand, can be cut from one turn in one inch to one turn in 100 inches, by both simple and compound gearing. For every-day practice, the range of simple-gearled spirals is amply sufficient, and the gears are as readily changed as on an ordinary screw-cutting lathe.

The spindle is of forged crucible steel, hollow its entire length, and the front end threaded, and hole tapered, so that arbors and chucks, fitting spiral head, will interchange with main spindle.

The spiral head is new in design, and so arranged that the elevation of its spindle to or near the vertical position raises the work as little as possible above the platen, and the arc through which it can be rotated in a vertical plane is 210°. It can be used on either end of the table.

The spindle of the spiral head is also hollow, pieces fifteen-sixteenths inch diameter passing clear through it.

The cone pulley has its smallest step toward the front, which permits the top of the column to slope upward toward the front-spindle bearing, bracing it and securing rigidity. The two spindle bearings are tied together by an arch at the top, which also supports the overhanging arm. A bearing nine inches long is bored in the arch, slotted at the top, and provided with two clamping screws. The arm can be quickly inserted, clamped fast, and as quickly removed.

The spindle boxes are of bronze, made in halves. They are cylindrical in form, with a deep rib running around the middle, faced square with the turned surface, and forced into a groove cut into the column and box cap. The outside of the box is finished entirely in the lathe, which makes its reproduction, when worn out, a simple matter.

The vertical adjustment of the knee is 14½ inches; in-and-out movement of platen (in line with spindle), 4½ inches; automatic feed, 18 inches; length of platen, including oil-pan, 33 inches; diameter of work taken on centers, 8½ inches; length between centers, 14 inches; size of front spindle bearing, 2 inches by 3½ inches; weight of machine, 1200 pounds. It is made by the Kempsmith Machine Tool Co., Milwaukee, Wis.

OF the collapse of the recent strike in the bituminous coal regions the *Coal Trade Journal* says: "The farce has been played, the tragedy has spent its force and the curtain has fallen. The chief actors have received their remuneration, even if the subordinates have not. As the net result of six weeks' idleness, certain of the coal-owners have made a million of dollars upon the stock on hand at the lake ports, as well as at those points on the Ohio where large stocks had accumulated. It was not anticipated when the strike was called that there would be so long a period of idleness, but the stocks in hand were larger than at first supposed to be the case. In certain districts the men get a few cents more than the rate which had been explicitly agreed upon previous to the unwarrantable calling out; their employers in the main can afford, temporarily at least, to give this, for not a few of them have been the gainers from the conditions existing in the past

six weeks. Other places have not been so fortunate (if this term may be used at all), for they have had to resume at old wages, after a loss of time that it will take years of steady work to recover; they have been duped, and, through the sympathy idea, have helped some one to pull the chestnuts out of the fire."

ACCORDING to the *Australian Mining Standard* of April

THE UNIVERSAL MILLING MACHINE.

28th, primary instruction would seem requisite in the case cited "where the English directors of a South African mine, in reply to their manager, who wrote to say that a new shaft was necessary, which he estimated would cost £500, said they thought the price was exorbitant, and enquired if he could not buy a second-hand one at a less figure!"

BUSINESS does not seem to improve as rapidly as was hoped. In general it would seem that what is most needed is confidence. Last year's scare is still in the air, and with unequalled resources industries languish. Confidence is a plant of slow growth, and easily uprooted.

The Nicaragua Canal.

The most important public work in reference to Coast industries is the Nicaragua canal. A bill for its construction is being drafted by the House Committee on Interstate and Foreign Commerce. It is thought in and out of Congress that the bill can pass both houses of Congress this session. Briefly, the bill provides that the old company shall call in and cancel all its stock, all outstanding obligations and contracts, all its debts, and when it shows to the satisfaction of the Secretary of the Treasury that it is free from all obligations he shall subscribe for \$70,000,000 worth of stock and call in all stock except the \$7,500,000 worth held by Nicaragua and Costa Rica. The directors shall issue that stock to the United States and also \$1,000,000 to such person as may be selected by the old stockholders as a bonus, and the company shall then issue no more stock. The terms of the present directors, except the two representing Nicaragua and Costa Rica, shall terminate, and the old stockholders shall name one director and the President of the United States shall name twelve, which shall constitute the board of directors. This number may be cut down to eight before the bill leaves the committee. Not more than one-half of the board shall be members of the same political party. The regular term of these directors shall be six years.

An accounting will be had with the old stockholders as to the amount they have expended, and when this claim is proved to the satisfaction of the Secretary of the Treasury stock equal to this amount shall be issued to them. This stock shall be non-assessable, and the Government reserves the option of buying it at any time by paying not to exceed its par value.

No dividend shall be declared on the stock except on the net earnings, and then it shall not exceed 4 per cent. The salary of the board of directors is fixed at \$4000 a year. The President, on the suggestion of the chief of engineers, shall detail three army officers from the United States Engineer Corps, one of whom shall be chief engineer in charge of the construction of the canal. He may detail such additional engineers as may be needed by the company in the transaction of its business. The intention is to have the bill provide for United States engineers making an estimate of the cost of construction of the canal in sections. The work shall then be done substantially, as river and harbor work is done here, except that it will be a continuous contract system.

It is the intention to have work begin at both ends of the canal at once. The bill will provide for the issuance of \$70,000,000 in bonds, to be disposed of as the work progresses, thus insuring means for the completion of the enterprise under this bill. The total capital stock of the company

will be \$83,000,000; \$7,500,000 will be held by Nicaragua and Costa Rica, \$70,000,000 by the United States, and the balance of the amount shown to have been expended by the old stockholders.

THE report of the directors of the Montana Mining Company shows that during the six months ending January 1, 1894, 32,553 tons of ore were reduced in the mills which yielded in bullion and concentrates an average of \$9.98 per ton, or \$324,726. The gross yield was 9728 ounces of gold and 95,855 ounces of silver. The total expenses for the same period were \$251,351, leaving a net profit of \$5494 for the half-year.

 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 397.

If the Governor of Colorado were to take to heart all the hard but well-deserved things the Colorado press say about him he would resign. He seems to be universally despised for his action, or inaction, in the recent mining difficulty at Cripple Creek.

A RECENT number of the *Popular Science Monthly* has an article alleged to have been written by "a scientific man," in which, as the twilight of evening ensued, "the crescent moon arose out of the waves in the East." A crescent moon rising in the East is so rare a phenomenon that the "scientific man" should vouchsafe further information regarding it.

THE twenty-second plank of the Republican State platform, adopted at Sacramento last Wednesday, favors the "free and unlimited coinage of silver at the ratio of 16 to 1." What is usually understood to be meant by "the ratio of 16 to 1," is this: The legal silver dollar contains 412.5 gr. standard silver, the legal gold dollar 25.8 gr. standard gold. Both are nine-tenths pure, one-tenth alloy. The gold dollar contains 23.22 gr. of pure gold, and the silver dollar 371.25 gr. of pure silver. The latter's weight is sixteen times the former, or, to be more exact, 15.989 times; hence, nominally, sixteen ounces of silver equals one ounce of gold.

THE New York *Financial News* asserts that for the first time in nineteen years India is exporting gold to England. In the course of a week or two the Bank of England will receive \$2,500,000 from that country. Under these circumstances, asks the *Record*, what becomes of the law which the goldites consider so inevitable, that the inferior metal necessarily drives out the superior? For nineteen years, while India was on a silver basis, there was no exemplification of this driving-out law, but just as soon as she is forced on a gold basis the law takes on an entirely new phase. The superior metal begins to drive itself out. How will the goldites explain this? The palpable explanation is that the gold basis policy of England for India was a crafty scheme to enable England to grab as much as possible of the gold of India, which probably amounts to nearly \$1,000,000,000, and to depress India to a still lower level of degradation and poverty. This is the effect which Chancellor Goshen predicted and denounced.

Production of Tinplate in 1893.

The following table, made up from Government reports, shows the total production of tin and terne plate in the United States during 1893 by quarters:

Quarter Ending.	(Tin and Terne Plate— Tin Plate.	Terne Plate.	(Black Plate Used— American.	Foreign.
March 31, 1893.....	15,294,557	14,324,825	11,381,968	78,194,431
June 30, 1893.....	20,748,427	18,705,191	13,354,725	21,279,352
Sept. 30, 1893.....	13,861,163	13,281,317	8,794,027	18,351,453
Dec. 30, 1893.....	14,682,045	12,669,195	15,907,693	11,443,572
Totals, 1893.....	64,586,192	59,070,498	54,337,389	69,268,818

"Risks of Mining."

This is an interjectional part of an article by Mr. F. H. Head in the current number of the *Forum*. Following his statement about the risks of mining to its logical conclusion, the risk is too great for any one to engage in mining, which is a palpable exaggeration. While there are risks in mining, the chances are no greater than in many other lines of business, for as a business proposition is the only way mining can be viewed. Mr. Head says "five-sixths of all the money expended in the effort to produce the precious metals is without return." This is a sweeping assertion, and one that cannot be successfully maintained. While men have lost money in the mining business, where one dollar has been fruitlessly expended one hundred dollars have been flung away in other branches of business. There is "risk" in everything. No line of business is exempt from it. Whether it be the railroad or newspaper; politics or steam transportation; electrical construction, agriculture, manufactures, merchandising, importing, exporting, building, real estate, anything and everything that involves the expenditure of money involves a proportionate risk. The collapse of the great Guion line is a case in point. A dozen years ago that great transatlantic company was putting millions of dollars in such flyers as the "Alaska" and other passenger steamships. They then held the ocean carrying trade, but within the year they have collapsed. The Atlantic is still there; the crowd of passengers is greater than ever; that business, certainly, is not "worked out." Yet Mr. Head would not desire to be understood that there is such "risk" in carrying passengers between America and Europe as to justify the steamship companies in quitting business. The collapse of great businesses all over the country is a matter of daily note. "Risk" was only one element therein. Management had considerable to do with it. A man can fool away money in mining as in other things, but it is believed by the writer that in place of there being too much "risk" in mining to justify the placing of capital therein, there is to-day no business in the United States that shows so small a percentage of failures; no business that offers greater or speedier return for the amount of capital invested than that of mining. If Mr. Head will take a few cold figures from Bradstreet or Dun and supplement them with similar reliable statistics, he will find fewer failures, less stagnation, better reports on invested capital, and in general a healthier tone in the mining industry than in any other. This may seem a good deal to say, but the facts justify the assertion. Even in the present fearful depression, with the world arrayed against three-fourths of the mining interests in the United States, the situation as a whole is less unfavorable than that of any other American industry; the prospects far brighter in the mining industry of the country than in any other branch of general business. When the existing dullness in all lines of business passes away, the mining industry will be first to feel the difference, and there is no branch of business to-day in this country in which capital can more confidently count upon satisfactory return than the mining business.

In no other business to-day is there such demand for the product; in no other business is there such freedom from competition; in no other business is there so wide a market; in no other business is it the rule that the sale is for cash to willing purchasers, and that he who sells is sought, not he who buys, the buyer being the seeker. Mr. Head further says: "Among the countless losses are a few enormous gains, when a genuine bonanza is found, and each producer expects that his turn will come soon. The great fortunes made by four or five Californians in the working out of the great bonanza in the Comstock lode nearly bankrupted the remaining population of the State in their endeavor to go and do likewise. It is like a lottery of which every purchaser of a ticket knows that less one-half the money paid for the tickets is ever refunded in prizes, and that there is not one chance in ten thousand that he will get back his money, yet the possibility of getting a thousand dollars for one is so enticing that lotteries have to be suppressed by law as a menace to the public morals."

In the above he simply confounds mining and gambling in mining stocks. The two are as distinct as wheat raising and dealing in "futures." True, were there no mining there would be no gambling in mining shares; true, also, were there no industrial corporations there would be no dabbling in industrial stocks, but Mr. H. is hardly ready to assume that because a clique can force down Reading or force up N. Y. Central, and "milk the street," that therefore railroad tracks should be taken up and all railroad building stopped.

(In justice to the article it must be said that that portion criticized is only an incidental part of it; with the article itself, "the need of an international monetary agreement," there can be no cavil, and all bimetalists will

agree with the deductions Mr. H. makes. The objection lies solely to that portion quoted, which seems to be unnecessary and out of place in an article of such general manifest value and force.)

Natural Laws Annihilated.

It is a common failing of mankind to rebel at the sphere which fate or Providence has assigned and yearn for another lot. The carpenter thinks if he were only a mason he would lead a happier life; the lawyer wishes he had studied medicine; the comedian feels that tragedy is his true forte; and the tiller of the soil wishes he were a miner and securing store of yellow metal from Nature's treasure house. This is not a new discovery. But there is a cognate principle not so generally understood. While it is true that many men regard themselves as eminently fitted for something better than they are doing, there are others who think themselves at their best in the vocation to which they have been called, but who are really capable of something infinitely better and more useful. There is that eminent Brooklyn divine, for instance, who lectured in this city on the 23th of last month. He is a born preacher and seems to be satisfied with his field of action. Yet it must be apparent to others that it is not his true sphere. His recent repeal and abolition of the law of evolution shows that he is capable of rendering mankind a far greater service than he possibly can by preaching, no matter how eloquently.

It is not much, perhaps, to wipe out the law of evolution. It has never annoyed the public a great deal. There has been some difficulty in that "harmonizing with the environment," which the law requires, and "the survival of the fittest" has occasionally created a natural discontent among those who were not classed with the fittest. But, on the whole, the law has operated so imperceptibly that it has not been felt as a burden. It has permeated the surroundings, of course, just as the recent destruction for the third time by fire of Dr. Talmage's tabernacle has created the general impression that Providence was more or less gently hinting to Mr. T. that his preaching was not wholly necessary to the plan of salvation, but all this has been indirect. On this account his action in wiping out the law of evolution is not likely, at first blush, to attract any marked attention.

But when the power involved is considered, the full force, meaning and significance of the act will be better apprehended. The man who can wipe out one natural law at a single stroke of his tongue, as it were, or a single sweep of his arm, can wipe out all laws that stand upon the same foundation. The mere statement of this conclusion shows what enormous power for good Mr. T. and such as he have, and how plainly it rests within their volition to become the chief benefactors of their race. Take again the example of that great and good man, the Scottish Prof. Robt. Stevenson, F. R. S., who lectured at the Academy of Sciences in this city last Monday night. He annihilated the law of gravitation, pooh-poohed poor old Isaac Newton, showed that Newton wasn't in it, so to speak, and that we had all been doddering along, supposing that there was such a thing as terrestrial gravity and the law of gravitation till the Prof. at the big stone building on Market street put forth his arm and smote that law which has hitherto bound mankind so immovably to the earth. Now this man has also mistaken his vocation. Instead of being an humble professor from a Scotch university, inventing flying machines, etc., he should, like the other law annihilator Talmage, continue in the line they have begun and smash sundry other irksome laws. There is the law of numbers, for instance, that decrees so savagely that two and two shall be four! What inconvenience and annoyance would the world not be spared if those two great repealers would relieve us from the humiliation that this law imposes! There is probably not a human being anywhere on the round globe who has not wished at times that he could make five or three by adding two and two. Let the men who have repealed the law of evolution and the law of gravitation repeal also the law which prevents such an arithmetical consummation, and receive the grateful thanks of the race. It may be that these two men, by leaving their present avocations and setting their minds solely to repeal, can even abrogate the great law of national cause and effect and give us back the prosperity that seems to have temporarily flown. The subject is a suggestive one.

SAN FRANCISCO will be well represented at the Chilean Exposition at Santiago next September, October and November. There is a good field there for the sale of mining and other machinery, and one worth cultivating.

THIS month has seen six sovereign States under martial law and terrorized by labor troubles. The trouble is mostly patched up, and now the afflicted commonwealths have the bills to settle.

Concentrates.

The mill at El Dorado canyon, Nevada, has closed down.

The recently rebuilt Bullionville, Nevada, mill has begun operations.

A small stamp mill is now in operation at the Healdeburg paint mine.

The Yellow Jacket, Idaho, quartz mill was totally destroyed by fire last week.

The Sonora Bonanza Co. of Tuolumne will resume operations on July 1st.

F. A. HEINZE, of Butte, has bonded the Deer Lodge mine in Jefferson county, Montana, for \$35,000.

The Bart and Bach mine, at Bear Valley, Mariposa county, has once more started up with a full force.

A San Francisco lady has opened the Big Crevice mine in El Dorado county, on the American river.

S. H. ROBINSON and H. C. SUMMERS, of this city, have bonded the Hancock mine, near Jackson, for \$15,000.

The Great Eastern quicksilver mine, near Guerneville, Sonoma county, has again resumed operations.

The Bisbee Copper Company has let the contract for grading its road between Fairbanks and Benson, Arizona.

"Keep away from Angels Camp," says the *Echo*. Business of all kinds and the labor market are overdone there.

CINNABAR said to contain fifty per cent of the pure quill has been found at High Ore gulch, Basin district, Montana.

The Bald Mountain Extension gravel mine, in Sierra county, yields an average of \$10,000 a month, and is worked cheaply.

The Bullion mill at Forbestown, which has been closed down for two or three weeks, will be started up again in a few days.

TWO HUNDRED tons of rock worked last week by the Standard Company at Oregon City, Butte county, average twenty dollars per ton.

The latest diamond find is reported from the Queen Charlotte Islands, but no immediate glut in the diamond market is looked for.

The Centennial mine on Duncan Hill has been sold by J. W. McCullough to a New York company. A force of men is reopening the claim.

The Denver *Record* declares that the best mining experts figure out \$620,000 in eight in the Victor mine at Cripple Creek, excluding the dump.

The Cripple Creek imbroglio has already cost Colorado \$200,000—to say nothing of the deterring influence that such lawlessness has on capital.

JOS. FRIEDMAN, of Merced, has bought the Hayseed and two other mines at Whitlock, and also two at White Rock, and has begun active operations.

The Poorman mine has had to close down because of railroad washouts in Canon creek. Superintendent Clark expects to resume work July 1st.

FROM a reliable source the Denver *Mining Record* learns that seven miners were put to sleep permanently during the late Cripple Creek scrimmage.

The Sierra Buttes mine of Sierra City has paid a twelve per cent dividend to its stockholders, and Plumas-Enreka mine an eighteen per cent dividend.

MORSE & SONE have resumed work on the Bunker Hill quartz mine. The *New Era* says they have recently placed some new machinery on the claim.

GRASS VALLEY has formed a Miners' Union, with the following officers: President, George Stacey; vice-president, Michael J. Owens; secretary, John Sullivan.

FROM the Bald Mountain Extension gravel mine at Forest City, last week, 141 ounces of gold was the result of the cleanup. Some of the gravel yielded \$30 to the carload.

H. B. CHAMBERLIN'S ASSETS were sold in Denver, Col., last week. They represented \$2,457,701.85. They sold for \$100. He wanted the earth, but collapsed last December.

NEW life is reported in the Pine Flat mining district, Sonoma county, and from present indications the famous mining district will soon take on some of its old-time prosperity.

NUOGARE weighing a quarter of an ounce have been brought into Olympia, Wash., by recent prospectors, who are very quiet as to the location of the find, but say it is very close by.

THE Miller mine, on Farmer's flat, Jackson county, Or., is about to be sold to Messrs. Dunphy, McCarthy and Bailey for \$12,000. The cleanup for this season will reach \$10,000.

THE Congress, Arizona, mine is now shipping about a carload of concentrates per day. Six teams of eighteen animals each carry the concentrates from the mill to the railroad.

RIVASIDE PAPERS say that the number of capitalists and miners of experience who are becoming interested in the mining regions of southern California is continually on the increase.

DANVAP papers say cyanide has been successful in treating the low-grades of the Denver gold belt, and a number of mills will be erected there this season. Its cheapness commends it.

THE Vekol silver mine, near Casa Grande, has closed down. Lucien E. Walker, one of the owners, died recently at Pasadena. The mine is reported to have produced over \$1,500,000.

A TWELVE-OUNCE NUOGAT was taken out last week from the old Casey mine, in Sawyer's Bar district. This is the mine from which a fine specimen, weighing nine ounces, was taken last year.

THE *Record* says: "Leadville, Col., will produce in the neighborhood of five million dollars in gold this year; Gilpin county is good for an equal amount, and Cripple Creek ought to pass the three million limit."

THE Chinese miners around Grangeville, Idaho, have been "salting" their gold dust with silver filings and quicksilver and selling it to the merchants of that place, who only got about 40 cents out of every dollar of gold dust.

THE Columbia Con. Gold Mining Co. at Yellow Jacket, Idaho, is about to build a ten-stamp mill. There are 20,000 pounds of

machinery at Ketchum, awaiting shipment by the way of Challis. The mill will be run by an electric motor.

ROBERT ELLIOTT, a miner, fell down a shaft at the Virtue mine, near Baker City, Or., last Monday, and was killed instantly. He fell over 200 feet, breaking nearly every bone in his body.

FROM a statement sent from the American Developing and Mining Company of Butte, Montana, it is learned that during the year ending May 31, 1894, the company made a net profit of \$419,235.81 in working the Golden-Sunlight mines.

THE exports of gold and silver from the port of Barranquilla, Republic of Colombia, for 1893 were: Gold and silver, various, \$786,401; bars, \$2,780,946; coins, \$216,095; gold dust, \$103,351. This is a total of \$3,885,824, as compared with \$4,342,002 in 1892.

A new shoot of ore has been struck in the Bellefontaine mine at Willow Valley. The *Transcript* says the quartz looks well and shows free gold. The owners think they have struck the old Beech shoot, from which Henry Beech obtained very rich quartz in '57 and '58.

THE old river channel near Bangor, Butte county, known as the Blue Lead, is rich in gold and many thousands of dollars have been taken from it. It is believed by many that this channel extends from Bangor to Wyandotte and through Wyman's Ravine to Oroville.

THE prospects in the prospect shaft at Dutch Flat, says the *Sentinel*, are continually growing brighter. From a single pan, the other day, a prospect of \$1.50 was obtained. Several little pieces of gold, ranging from 25 cents to \$3 have been found. The only thing needed now is enough of it.

CAMPO, San Diego county, has its monthly excitement over the alleged discovery of rich quartz and placer mines on the edge of the desert, sixty miles east of Campo, on the Picacho trail leading to the Cocopah mountains. The discovery was made by a Mexican and there are fifty men on the ground.

AT Mercur, Utah, last week the Marion Company retorted their sulphides, producing a gold brick. One of the results of the operation was about seventy pounds of quicksilver, among the first mercury produced in commercial quantities in any State east of this. The quicksilver alone was enough to pay the entire expense of retorting.

PREST. M. H. DAY of the Plumas Imperial Gold Mining Co. has bought a half-interest in five recent locations on the North Fork. Messrs. Westfield & Boyle of Nevada—the latter named the superintendent of the Alta mine on the Comstock—had been negotiating for the property, but delayed, arriving one day after the deal was closed. The property will be developed forthwith.

DURING a thunder storm at Grass Valley last Saturday night the lightning struck the pipe in the Empire mine and descended into the mine to a depth of a thousand feet, and thence into the drifts where the men were working repairing the air pipes. Two of them, in lifting a piece of pipe, were struck by lightning and knocked down. The *Union* says men working in the Granite Hill mine were similarly affected.

SIX men arrived here Wednesday from Ferguson district on their way north, says the *White Pine News*. They say there are six men there for every job. All are hanging on their eyebrows waiting for De Lamar, and unless he puts in an appearance soon there will be some getting out of there. All the available timber within forty miles of Ferguson district has been located in anticipation of a rush of business.

AT the Santa Rosalia copper mines, across the Gulf of California from Guaymas on the Baja California peninsula, are employed about 1200 men. There is a narrow-gauge road fifty kilometers in length to carry the ore to the smelter. About 1000 tons of copper are monthly shipped to Europe. The company pays large dividends. So far as any benefit accrues to this country the mine might as well be in New Zealand, though it is at our door.

"GOLD is a precious metal," explained the professor, "because of its scarcity. All the gold now in use in the world," he added, referring to a memorandum on the fly-leaf of the textbook he was using, "according to careful and trustworthy estimates, could be put within the walls of a room twenty-four feet square." "So could all the silver in the world," suggested a little red-headed boy in the class, "if you make the ceiling of the room high enough."

THE Jacksonville, Or., *Times* says Dr. Friedline and Mr. Kelly of Moscow, Idaho, are there with a patent sluice for saving flour gold. The machine consists of a double sluice-box in the form of an open-ended square, which is placed at the end of the sluices usually used. The water is divided and runs through a box on each side in which are placed screens loaded with mercury which catch what gold has escaped above. The machine has been used in Snake and Salmon rivers for the past few months and is pronounced to be a success.

A. J. McPHETRES found a 100-pound tank of quicksilver at the head of Donner lake a few days ago. It had been buried and only a little of the iron tank stuck above the surface. Against this projecting surface Mr. McPhetres accidentally struck his foot, and an investigation unearthed the tank nearly full of quicksilver. It was probably left there, says the *Truckee Republican*, by teamsters before the railroad was built, as they sometimes unloaded a part of their load before going over the summit. It has been shipped to Nevada City, where it will meet with a ready sale.

AMONG recent Northwest mining incorporations are the following:

The Phoenix Gold Mining and Milling Co., Baker City, Oregon. Capital stock, \$350,000. Incorporators, K. K. Kennedy, H. Holcomb, J. L. Rand.

The Northwestern Milling & Mining Co., Spokane, Wash. Capital stock, \$750,000, with shares at \$100 each. Incorporators, M. M. Cowley, J. Hoover, M. Thompson, S. R. Stern, W. B. Roberts, L. W. Johnson, S. Oppenheimer.

The Birch Conlee Placer & Quartz Gold Mining Co., Seattle, Wash. Capital stock, \$2,500,000. Incorporators, F. F. Reed, G. W. Adrian, R. O. Reed.

THE Lost Cabin, Utah, mine has been found again. This time only the ashes and a few pieces of logs remain to mark the spot where the cabin stood. A lot of picks, shovels, a broken Winchester, an old-fashioned six-pistol, some bones and a lot of empty cartridges were found in the ashes. The ruins are said to have been found near the headwaters of Ashley, in the

neighborhood of Bald mountain, and it is supposed that a party of miners met an untimely end while fighting for their lives, against whom the public may never know. A tunnel thirty feet long was found near the ruins of the cabin; it had been well timbered, but the timbers had rotted away, which indicates that many a year had elapsed since the mine had been worked. The tunnel was cleaned out, and a fine body of rich-looking ore was found, a sample of which has been sent to Salt Lake for assay.

Clipped and Condensed.

THE closing exercises of the Midsummer fair as an entirety will be on July 4th.

THE report that the revenue cutter *Esar* was wrecked off Sitka proves to be a mistake.

AN alleged conspiracy to blow up the Government buildings has startled the national Capital.

UNITED STATES SENATORS QUAY AND McPHARSON surprise the Senate by admitting that they have been financially influenced by the sugar trust.

IT is estimated that railroads and cities of the Northwest will have to expend \$4,000,000 to repair the damages done by the floods.

Nearly 200 miners were instantly killed and others fatally wounded by an explosion of fire damp in the Franzeiska mine at Kerwin, Silesia, last Saturday.

A suit in equity has been filed in the United States Circuit Court, in Los Angeles, by Loren Jones of New York against Mrs. Jesse Benton Fremont, widow of General Fremont, the Pathfinder, to restrain her from collecting money from Congress for the seizure of land by the Government belonging to her husband.

THE Attorney-General, Olney, has determined to enter suit against the Union Pacific and Kansas Pacific jointly and the Central Pacific Railroad to recover the amount of bonds which are guaranteed by the Government, together with accrued interest at 6 per cent for thirty years. The total amount for the three roads, including interest, is \$171,006,537.

QUICKSILVER does not go on the free list. In the Senate last Tuesday, Lodge moved to strike quicksilver from the free list and restore the duty of 10 cents per pound. Perkins said over \$30,000,000 was invested in quicksilver mines. The amendment was adopted—23 to 20. Quicksilver was placed on the dutiable list at 7 cents per pound on motion of Perkins without division. The smallest favors thankfully received.

HERR LUDWIG BAMBERGER of Berlin, an eminent authority upon the question of bimetalism and a member of the silver commission, declares, says a cablegram, that after twenty-one days of earnest discussion, no tangible result has been arrived at, but the meetings of the commission have furnished overwhelming proof that in the future no conference, either national or international, will arrive at a different result. According to Herr Bamberger, an understanding upon bimetalism seems to him impossible between the different states of Europe, including England or without England. He says the difference of the interest of the different countries precludes any satisfactory agreement.

THE Republican State Convention at Sacramento last Wednesday nominated M. M. Estee of Napa for Governor. The nineteenth and twenty-second planks of the platform are as follows:

The mines of California, with their annual output of many millions of dollars, have been our financial backbone in times of adversity; they maintained the national credit during the dark days of the Rebellion, and they form the basis upon which this grandest of commonwealths, California, has been reared. The mining industry of our State should receive such aid and protection as will insure its permanence and prosperity, and for that purpose we favor such State and national legislation as will relieve the miner from unnecessary hardships, enable him to obtain and develop his mining property, and will promote and encourage the business of all kinds of mining, including that known as "hydraulic mining," whenever and wherever the same can be carried on without material injury to the other interests in the State.

We favor the free and unlimited coinage of silver at a ratio of 16 to 1, and the making of silver as well as gold a legal tender in payment of all debts, both public and private, and we pledge our Congressional nominees to the support of the principles contained in this resolution.

Personal.

HON. FRANK MCCOPPIN has been appointed postmaster at San Francisco.

THOS. DILLON is now superintendent of the Boss mine, at Sweetland.

D. A. MACDONALD, "Alex. Quartz," has gone on a prospecting trip through Butte, Plumas and Shasta counties.

FRED CAWTHRA, president Gaston Mining Company, of Silverton, Colorado, has gone to London.

JOS. GAUNDAKMYAR of Hamilton, Nev., has a good exhibit of the White Pine ore at the Nevada building at the Midwinter Fair.

F. A. HUNTINGTON has been taking a trip through southern Oregon, and while there bought a one-half interest in the "Bone of Contention" mine on Williams creek.

PROFESSOR SNEYDER and A. C. ROUTH, with two saddle and three pack horses, left Pullman, Idaho, Wednesday morning for the wilds of Idaho and Montana on an expedition for Stanford University of California. Mr. Snyder has been commissioned by the university to collect a full line of specimens of the smaller mammals of the districts which he will visit for the museum of the institution. He will be absent all summer.

JIM TOWNSEND, of the *Homer Index*, is taking in the Midsummer Fair. He says he left the *Index* all set up and printed and full of local matter for three weeks ahead, and is here to look after his flying machine, one of the greatest inventions of the age, surpassing anything in the line of perpetual motion ever talked of. In order to bring it to a standstill after getting it once started one has to begin stopping it six hours before starting it.

Digging Gold With a Steamer.

Extravagant stories are told about the wealth of gold sprinkled through the Snake River country in Idaho. As a general thing the gold is very fine, the particles being of so light weight as to be elusive. Save when worked on a large scale it is difficult to make good wages in recovering the gold. Numerous bars along the river would prove profitable could water be commanded for sluicing or hydraulicking. An adequate supply is hard to obtain, from the slight gradual fall of the stream and level character of the outlying lands. To overcome this lack of water, as well as to insure sufficient dumping grounds, a big, floating gold-saving dredge has been constructed and is at work on the Idaho bank of the river, about ten miles above the Payette. It is a stern-wheel flatboat, propelled by steam. Substantially constructed, 65 feet long and 22 feet wide, it is equipped with a 35-horse power machine engine and boiler, and adapted in every way for navigating Idaho's great waterway. With a slight alteration it could be transformed into a steam dredge and used to scoop up sand and gravel from the bottom of the stream. As in the past, operations are now confined to working bars out of the channel of the river.

The method pursued is to anchor alongside one of these gravel deposits and by the use of scrapers bring the material to be handled within reach of the gold-washing machinery with which the craft is rigged. The gravel is scooped up by buckets attached to an endless chain. There are forty-eight of these receptacles on a belt sixty feet in length, and each has a capacity of about twenty pounds of dirt, which is delivered into a hopper. This is also an agitator, and the process employed may be described as a steam rocker with the exception that it has an end motion instead of one sidewise. The gold is caught on copper plates with quicksilver. The tailings are carried off in sluice boxes by a stream of water of 150 mineral inches, supplied by a China pump run by the engine which drives all the other machinery. The gravel is worked so thoroughly that no gold escapes in the tailings that are dumped into the river. An average of 100 tons of gravel are handled, and for this work three men are employed. —N. W. Mining Review.

1849 and 1894.

From the upper big bend of the Columbia to the Siskiyous of southern Oregon come reports of extraordinary activity in the placer mines—such golden yields as have not before been taken out in a quarter of a century. Without question the year 1894 will be second only to the golden era of 1849-50. This will be due in part to the enhanced value of gold and the cheapness of provisions and supplies, together with the opening up of new lines of transportation; in part to the diminished interest in quartz mining, which has sent an army of prospectors panning out the golden bars and gravel, and in part to the extremely high water, which enables the miners to work the higher and richer bars hitherto left untouched, and at the same time cuts new channels and tears out old auriferous drift and deposits.

In the feverish rush of 25 and 30 years ago the country was barely scratched over. A great deal of ground was overlooked, and vast areas that were unprofitable with flour at 25 cents a pound, and all else in proportion, will now give profitable returns. The Chinese followed in the wake of the early miners, it is true, but they are poor prospectors, slow workers, and cling to primitive methods, and, besides, were unable to get at the higher bars and benches.

It must not be assumed, though, that every man can take a pick, shovel and blankets and go out and find "ounce diggings," or wash out big wages. That was impossible even in the flush days of California. Some men cannot succeed at anything. When thousands of miners were working ounce diggings along the Feather and the Yuba, hundreds were "dead broke" down at the bay. Nevertheless, many will make placer mining pay, and some will take out handsome little fortunes.

There is something about placer mining that calls out the best traits of American citizenship. It fosters a rugged independence and cultivates an admirable respect for law and manhood. The placer miner seldom allows the professional agitator to lead him around. He despises tyranny and has no use for "bums," is free-handed and generous, and not given to chronic grumbling. His labors will do much this year to restore prosperity. That he may enjoy success is the wish of all. —Spokane Review.

Single-Valve Cross-Compound Engine.

The illustration on this page is of a Jackson Patent Single-Valve Cross-Compound Engine, with air pump and jet condenser direct, connected to centrifugal pump, discharging under (left-hand view), and put on Senator Wm. Johnson's place at Courtland, Cal.

Water and Gold.

Probably few persons, even among the old settlers, know of the existence of a subterranean lake in the San Gabriel canyon, says the *Azusa News*. Yet one exists, and moreover it contains gold in no mean proportions. It is situated on the north side of the east fork about one mile above Cornelius Potter's ranch, on what is known as the Don Felipe mine. It is about 50 feet above the river and about the same distance below the surface. The basin was discovered about twenty years ago by some Spaniards who were drifting into the hill in search of placer gold. Since then different parties have made developments that serve to define the exact boundaries of the water. On each side of the hill on which the lake is located are narrow gulches. A tunnel has been driven through the hill and opening into both gulches, forming an opening through the hill. From this tunnel drifts have been run in every direction just on top of the water, leaving the gravel and water underneath. In some places deep holes have been dug down into the basin and the gravel extracted, which proved to be very rich in gold. It is claimed that some gravel taken from this basin paid as high as \$5 to the pan. The hill has been completely honey-combed by drifts, and the roof is in a very bad condition, some places having caved very badly. Persons who prospected the basin claimed that it had been

now go out with a few dollars and return with several hundreds or thousands. Some of them will make nothing better than wages, but when several thousand men put in a summer washing golden bars and channels, some of them are going to discover rich pockets and a few real bonanzas, and that adds amazingly to a country's prosperity. —Spokane Review.

The Bell Cord to Be Relegated.

The Southern Pacific company is arranging all the passenger coaches on its lines with an air contrivance by which a small whistle in the cab of an engine is caused to sound a warning to the engineer that he shall stop the train, says the *Record-Union*. The air whistle will take the place of the bell cord now in use on trains, and the change is made on account of the unreliability of the gong to sound in the engine cab when the bell cord is pulled, especially on long trains. The whistle is used by a number of large railroads in the East, and it will be but a short time before all the engines and cars of the Southern Pacific company will be equipped with it. It is operated by pressing a button.

Recent Specimens Received.

Interesting and valuable specimens are constantly being

JACKSON'S PATENT SINGLE-VALVE CROSS-COMPOUND ENGINE.

caused by the river, which at some time must have been very high, and that after washing the hole the current changed, filling it with debris. Several parties have been looking at the lake recently with the intention of draining it, and they all agree that the prospects are favorable for a rich strike, but it is in a bad condition to work. The best and about the only way would be to drive in from below and tap the basin underneath, and then work out the gravel through this drift.

Washington Placer Mining in '94.

Not since the rush to Bolse basin and the stampede to the upper Columbia in the early '60s has there been such activity in the placers. Hundreds of old diggings, mined superficially in the feverish days of 30 years ago, and abandoned because of a hope of better things and the excessive price of supplies and provisions, are being reclaimed and worked with profit. A great deal of virgin ground is also being staked out and developed, and in many places improved appliances and machinery return profits where primitive methods failed. The extraordinarily high water also makes it possible for miners to get at very rich ground hitherto beyond reach.

Perhaps this is better for the country now than prospecting for quartz ledges. In their search for quartz bonanzas the prospectors have run ahead of development. Their finds giving no immediate returns a great deal of costly energy has been expended with no compensating returns. The movement to the placers reverses this procedure. Instead of going out in the spring with several hundred dollars and returning in the fall with nothing, the prospectors

received at the rooms of the State Mining Bureau. During the week, among others, has been received a sample of lazulite from L. Gleichen, San Diego county, the first time the existence of this mineral has been noted in California.

Obituary.

A. B. Emery, a well-known Utah mining man, died in this city of Bright's disease last week.

Amos Bowman, geologist and mining engineer, died at Anacortes, Wash., last Tuesday. About twelve years ago he was assistant editor of this paper and was a capable and painstaking man.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894 by Henry G. Hanks, F. G. S.

Natural gas has been known to man from the time of the earliest historical writings.

The Persian sacred fires were burning in remote ages. Emanations of carbonic acid gas and sulphuretted hydrogen in northern Italy, and in the neighborhood of the bay of Naples and on the island of Sicily, were known in the time of the earliest European historians.

On the western shores of the Caspian sea, in latitude 40-23 north, and longitude 49-53, at the termination of the Caucasus mountains, lies the ancient town of Baku. There are numerous mud volcanoes and petroleum springs on the peninsula of Apsheron. Near these springs lies the celebrated "field of fire," which was held in extreme veneration by the Parsee fire worshippers. Pilgrims from Persia still make devout visits to this locality—a remnant of an ancient custom. In ancient times a blue flame of natural gas burned in one of the temples, from the end of an earth-inserted bamboo pipe, which was regarded by fire worshippers as eternal. That it did not burn the Parsees seemed to them miraculous—at least it was believed that the sacred fire would burn as long as the world endured. Emanations of gas were so general that the priests could at any time and at almost any place, by making a small opening in the earth, collect gas in a bag and carry it away to be burned like coal gas at the present time. The flames sometimes, when the generation of gas was unusually copious, would play over a large area and seem to roll down the mountain sides.

Dr. James Mounsey, in a communication to the Royal Society of London many years ago, described the "Sacred fires of Persia," near Baku. "If a little of the surface of the earth is scraped off, and fire be applied to the hollow, it catches fire immediately and burns without intermission and almost without consumption, nor is it ever extinguished unless some cold earth is thrown over it, by which it is easily put out. But the most remarkable spot is a hole about four feet deep and fourteen in diameter. In this cavernous live twelve Indian priests and their devotees, who worship the fire, which according to their traditions has burned many thousand years. It is a very old vaulted building, and in its walls are a great many chinks, to which, if a candle is applied, the fire catches instantly, and runs instantly wherever the chinks communicate, but it may be easily extinguished. They have hollow places in the house fitted to their pots, which they boil without any other fuel, and instead of candles they stick reeds into the ground, from the tops of which, by applying fire to them, a white flame immediately comes forth and continues to burn without consuming the reeds until they think proper to extinguish it by putting small covers over it for that purpose."

The Chimæra of Lycia, near Deliklitas in southwest Asia Minor, at the site of the ancient Phaselis, was a place where flames burned continually. The ancients manifested a superstitious interest in this locality, which is mentioned by numerous writers. It has recently been visited by travelers and found to be a gaseous emission resembling the fires of Barigazzo and the gas fountain in Colusa county, California.

The mythological Chimæra was a horrid monster which continually vomited fire; one part of the body and the head were those of a lion, another part was that of a goat and the third was that of a dragon.

The following is Pliny's account of it (Book 2, chap. CX): "In Phaselis the mountain Chimæra burns with a continual flame day and night. Ctesias of Cnidos informs us that this fire is kindled by water, while it is extinguished by earth and hay. In the same country of Lycia the mountains of Hephestus, when touched with a flaming torch, burn so fiercely that even the stones in the river and the sand burn while actually in the water. This fire is also increased by rain. If a person makes furrows in the ground with a stick which has been kindled at this fire, it is said that a stream of fire will follow it."

The following is quoted from the *Iliad* of Homer: "First dire Chimæra's conquest was enjoined, a mingled monster of no mortal kind. Behind a dragon's fiery tail was spread, a goat's rough body bore a lion's head. Her plucky nostrils flaky flames expire, her gasping throat emits eternal fire."

Beleroëphon, banished from Lycia by Proteus, was sent to combat with the Chimæra, by which it was expected and desired he would surely be destroyed. But by the aid of Minerva and Pegasus he conquered. The myth is supposed to have originated from the fact that the burning mountain of Lycia near to the summit was a wilderness, in which lions lived. At a lower altitude the land was fertile

and herds of goats grazed in safety, while at the bottom the marshy lands were infested with serpents. Beleroëphon conquered by living on the mountain in spite of the lions and the serpents.

Ovid thus refers to the Chimæra: "And now she left Cragos and Lymre and the waters of Xanthus and the mountain where the Chimæra had its middle parts fire, the breast and face of a lioness, and the tail of a serpent. (Met. 9-645.)"

"And now the goddess, wearying with her long toil, being parched with the heat of the season, contracted a thirst in the country of Lycia, which has the Chimæra in it, where the violent sun scorched the fields." (Book 6-839.)

Pindar, in his thirteenth Olympian Ode, thus alludes to Beleroëphon and the Chimæra: "And of a truth the gallant Beleroëphon with blythe soul grasped the winged steed, around his neck casting the gentle charm. Straight mounting, clad in brass, he rode the warlike; with him he slew the fair host of Amazonian archers, heaving his shafts from the bosom of the cold desert air. He slew alike the Chimæra, breather of fire, and the Solymi—his own fate I shall pass: the courser Jove's stalls in Olympus received."

In the metamorphoses of Apuleius (Book 8) may be found the following allusion to the Chimæra: "My lively gait, however, proceeded not from alacrily, but, on the contrary, from fear, though I consoled myself not a little by reflecting that fear, perhaps, caused the most celebrated of horses, Pegasus, to leap all the higher when panic-struck at the teeth of the fire-vomiting Chimæra. He made a wonderful spring into the air that carried him clean to the celestial regions and acquired for him his poetic reputation."

Lucretius evidently did not believe in the Chimæra, judging from the following quotation (*Nature of Things*, Book 5):

"Since flames will scorch a lion's breast
And burn as well as any meaner beast,
How could Chimæras rise, or how contain
Three kinds, a lion's head, a serpent's tail,
A goat the middle of the fancy'd frame,
And still with scorching coostils breathing flame?"

Captain Beaufort, in command of an English survey of the coast of Lycia in 1811-1812, published a description of the south coast of Asia Minor (Karamania, London, 1817), in which he describes this fire, the modern name of which is "Yanner."

Fol. 45: "We rode about two miles through a fertile plain, partly cultivated, and winding up a rocky and thickly wooded glen, we arrived at the place. In the inner corner of a ruined building the wall is undermined so as to leave an aperture about three feet in diameter and shaped like the mouth of an oven. From thence the flame issues, giving out an intense heat, yet producing no smoke on the wall; and, though from the neck of the opening we detached some small lumps of caked soot, the walls were hardly discolored. Trees, brushwood and weeds grow close round this little crater, a small stream trickles down the hill hard by, and the ground does not appear to feel the effect of its heat at more than a few feet distant. The hill is composed of the crumbly serpentine already mentioned, with occasional loose blocks of limestone, and we perceived no volcanic productions whatever in the neighborhood. * * * Our guide asserted that in the memory of man it had never changed its present size or appearance. It was never accompanied, he said, by earthquakes or noises, and it never ejected stones, smoke, nor noxious vapors, nothing but a brilliant and perpetual flame which no quantity of water could quench. The shepherds, he added, frequently cooked their victuals there and he affirmed with equal composure that it was notorious that the Yanner would not roast meat which had been stolen. * * * This phenomenon appears to have existed here for many years, as unquestionably this is the place to which Pliny alludes in the following passage: 'Mount Chimæra, near Phaselis, emits an unceasing flame that burns day and night.'"

Captain Beaufort describing "the great mountain of Takhtain" adds (fol. 55): "They have also a tradition that when Moses fled from Egypt he took up his abode near this mountain, which was therefore called the mountain of Moses. May there not be some connection between this story and the Yanner already described? That place and the mountain are not many miles asunder and the flame issuing from the thicket, may have led to some confused association with the burning bush on Mount Horeb, recorded in Exodus."

(To be continued.)

A Little Truth—Considerable Exaggeration.

A Swiss writer who visited the World's Fair, and remained for some time, writes in a recent issue of the *Neue Zürcher Zeitung* under the headline "What Is America?"

"America is a land compared with which Europe is only a peninsula; the United States forms a country compared with which the European kingdoms are pilgrims. America

is the land of unmeasured distances and dimensions; the land of dollars and electricity; the land where the prairies are more extensive, the rivers mightier, the waterfalls deeper, the bridges longer, the lightning expresses faster, the catastrophes more terrible, than in any other country in the world. It is the land where in a single railroad accident—and one occurs every few days—more people lose their lives than in Europe in a whole year. It is the land where the houses are higher, the 'jallhrds' more numerous, the rich richer, the poor poorer, the millions greater, the thieves more daring, the murderers more shameless, the educated fewer, the teeth more generally false, the corsets narrower, the disease more deadly, corruption more general * * * the summers warmer, the winters colder, the fires hotter, the ice thicker, time more precious, the men more nervous, than in any country in our pastoral Europe. It is the land where the old men are younger and the young men older, the negroes blacker, the whites more yellow than in any other place. It is the land of immeasurable natural wealth. In short, it is the land of extraordinary contrasts, of strange extremes of nonsensical pride, of reckless money-hunting, of senseless craze for gain—the land of the colossal and the pyramidal—of course, in the opinion of Americans. How many have gone from our peaceful home to the land of false hopes to seek riches, fortune and better life and have been lost, either in the gutters of the great cities or the sands of the prairies! How many have been glad, when poor and deserted and broken in heart and soul, to sail back to their native land!"

In the Cœur d'Alenes.

J. F. Poynton, of the Cœur d'Alene mining district, who was secretary of the central executive committee of the Miners' Union during the time of the trouble between the miners and mine-owners, reports everything quiet in the Cœur d'Alene district now. He asserts that the miners are contented with the existing condition of affairs and with their wages, and show no desire to repeat the strike of '92.

"There was a rumor that the miners at Wardner would go on a strike, but it was utterly without foundation," he says. "The report was started and industriously circulated by a few malcontents, who disliked the distinction between skilled and unskilled labor made by the mine-owners of Wardner. There the skilled miners receive \$3 50 per day, and the carmen and shovelers \$3, while at Burke and Gem all the men receive \$3.50 per day. Some one set up a clamor that the Wardner carmen and shovelers were working for less than the usual wages, and asserted that the scale, which had always been considered just and equitable, was unjust. The cry was taken up, but was speedily quelled by the conservative miners, who are in the majority. They were perfectly satisfied with the scale, and would listen to no strike proposition which would disturb the affairs of the district and force many men who are willing to work out of employment. The time appointed for the strike has passed, and the men are still at work, and all the miners are satisfied with the premium on skill offered by the Wardner mine-owners, which those of Burke and Gem do not offer."

He says the Poorman, Tiger and Standard mines at Burke, the Gem and Frlsco at Gem, the Bunker Hill and Sullivan at Wardner, are running on full time day and night, and give employment to about 1100 miners and 300 outside men. "The Bunker Hill and Sullivan, which is the largest of the six, employs 350 men. The output of the mines is very large. The Last Chance and Tyler at Wardner, which are closed on account of litigation, will probably be opened soon. The Morning and Hunter mines at Mullan will also shortly be reopened, and will give work to about 300 men. There are very few idle men in the district now, and when operation of these mines is resumed, we will have to draw on other parts of the State for miners. Some of the Coxeyites might get work there, but as they showed no disposition to engage in manual labor when they were in the State, it is doubtful if they would accept it. However, plenty of miners can be had from other States. Many arrive from Colorado, Arizona and New Mexico every week and readily obtain work. Most of them are surprised to find what a prosperous district we have, and astonished to find how much it exceeds their own States in prosperity."

"Very little Eastern capital has been invested in the district lately, owing to a fear of a repetition of the labor troubles and the uncertainty involving the future price of silver. There are plenty of good prospects, which, when times grow better, will be taken up and developed by Eastern men. The usual amount of development work is being done on all of the old mines, with the usual discovery of richer ore than was expected."

"The owners of the quartz and placer gold properties on the North Fork of the Cœur d'Alene think that this will be the most profitable season they have ever had."

Electrolysis—Its Cause and Cure.

So much local interest has recently been manifested in the matter of electrolytic corrosion of gas and water pipes by the return currents of electrical street railways that the following is timely, it being the embodiment of a report of a committee specially appointed to inquire into the subject:

A thorough appreciation of the principles of electrolysis being necessary to the proper explanation of the effects observed, your committee may be pardoned by repeating some details which may be already familiar. Practical employment of the phenomenon of electrolysis is made in electro-plating, in the Edison electric meter, in the reduction of aluminum and other metals from their oxides, in the purification of sewage, etc., but the condition of its application most similar to that which we are now considering is exhibited in the well-known laboratory experiment of analyzing water by the passage of an electric current between poles immersed in the acidulated liquid, for electrolysis literally means a loosening or dissolving by electricity. These poles are called *electrodes*, the positive pole being the *anode* and the negative the *cathode*, while the liquid is termed the *electrolyte*. In the instance cited, if the object of the experiment were the production of hydrogen and oxygen, platinum poles would be employed; but if a more easily oxidizable substance were used for the electrodes, the conditions present in the analogous system of electro-plating would be produced—that is, there would be a perceptible wasting away of the substance of the positive pole, and a gradual accretion at the cathode or negative terminal. The electrolyte must be a compound substance, and in a liquid state, either by solution or fusion. When a salt is electrolyzed, the acid always appears at the positive pole and the base at the negative. In the case of water, the collection of the hydrogen at the negative pole is but another instance of its metallic behavior, and the oxygen always collects at the positive pole.

Turning now to the phase of electrolysis which we have to consider, we may briefly summarize its history by remarking that telegraphic practice had led electricians to think the earth's resistance practically nothing; hence in the earlier electric traction installations, no special attempts were made to provide for returning the currents to the power-houses. But the necessity for such provisions was soon apparent, and a form of bond wire for connection at rail-joints was introduced, the tracks being relied upon as return conductors. The use of a supplementary wire between the tracks, larger bond wires, and more attention toward securing electrical contact, followed, but with increased experience in electric-railway work, came the realization that these attempts had been little better than makeshifts, and that owing to imperfections and consequent resistance, a large proportion of the current was seeking other avenues of return, and was causing injuries by so doing.

The realization of this condition by no means came all at once, for railway managers were at first loath to believe the operation of their dynamos responsible for the reported damages to the telephone cables and gas and water pipes, but ascribed the corrosion to chemicals in the soil or other causes, and doubtless looked upon the loss of their current as a necessary evil attendant upon the method of propulsion employed. Some of the earliest experiments to locate the source of this corrosion were those of Mr. I. H. Farnham of the New England Telegraph & Telephone Company, Boston, who exposed short lengths of cable to all the conditions affecting the corroded cable, except that of connection with the system of wires, and found them unaffected after an exposure during which the neighboring connected cables were badly injured. Many other tests have been made, and there is now a full agreement by both the owners of the buried pipe and wire systems and the street-railway people as to the cause of the trouble, all uniting in ascribing it to the earth returns of the enormous currents used in electric traction.

Having agreed that the grounded current is responsible for the injuries we have observed, let us see the manner in which it acts. No effect is produced where the current reaches the pipes, for this is a negative electrode, and would be receiving a deposit from the rails and bond-wires, if any action were apparent. Neither is there likely to be any damage in the body of the pipe, unless a small connecting line should be encountered whose greater resistance would cause heating, or the presence of joints of higher resistance (due to leaks, or the use of cement) should force the current out, to return a few inches farther on. But the injurious action occurs at the point where the current leaves the pipes to enter some conductor offering an easier path. This will usually take place opposite the power-house—where the current is also greatest in quantity, owing to the accumulated returns from the entire line—and at points where pipes cross beneath the tracks, the current returning to the rails with especial readiness if the direction of the pipes no longer coincides with that of the railway. Here

the conditions of our laboratory experiment are reproduced. Of two points where rails and pipes are equally distant, the greater flow of current will take place where the greater moisture exists. This moist earth then is our electrolyte, made specially effective by the gas, ammonia from animal refuse, salt from melting snow, or other chemicals present in the ground; the pipe is our anode, and the rail or other objective point of the current the cathode. The metal of the anode or positive pole is gradually carried in the direction of flow of the current; and the electrolysis once begun, the oxygen and ozone of the electrolyzed moisture collect at the positive pole and aid in attacking the pipe. The rapidity of its destruction depends on the quantity of current passing rather than upon its voltage; and instances are on record and in the knowledge of your committee where a single month sufficed to destroy new service pipes.

Verbal expressions from several sources, as well as certain published discussions, seem to indicate that the full extent and effect of this electrolytic trouble is but vaguely realized by many of us. Some of us may think that not having found any ill effects ourselves, the question, though an interesting one, deals with a matter that does not touch us directly. Your committee would emphasize this statement, that no city in which an electric road is operating with any part of the return through the ground, has its gas and water pipes wholly free from electrolytic action; the fancied immunity is the security of incomplete information. To draw attention to the widespread nature of the trouble, a portion of the appendix accompanying this report is devoted to published accounts of damaged pipes. The greater number of complaints come from the water interests, for two reasons; first, greater conductivity, for the water mains range greater in size than gas mains, the absence of cement joints decreases their resistance, and the contained water may add to the conductivity; and second, the greater pressure carried more quickly occasions a break. But the gas mains are beginning to indicate the action upon them, and will do so more and more unless effective remedies are soon applied. When we realize not alone the immense capital buried in our water and gas distributing systems, but the fact that street improvements have made repairs to our pipes additionally expensive, we may begin to appreciate the serious character of a condition which divides by 5, 10, 50, and even 100, the life of a pipe, and which, until the cause be removed, may repeat the operation on the replaced line in an equally short time, or accomplish a similar injury at another point where its action will be less readily located.

Coming now to a consideration of the remedies, we will first notice those which have been suggested for adoption by the gas and water companies. Probably the earliest of these was that of coating the pipes with non-conducting paint or a covering of similar purpose. A parallel of this is the use of drain pipes of slightly greater diameter than the metal ones, slipped over the latter and cemented at the joints and at ends. These have been adopted with special convenience for service pipes crossing under the rails, but their value is dependent upon the local circumstances. If the corrosion at such a place is caused by the current flowing downward through the earth and so entering and leaving the service at about the same points—placing it in an electric bath, as it were—such a covering should prove a true protection. But if the current had reached the line through some imperfection at a point farther away, and caused the corrosion by leaving the pipe to return to the rail, any insulation, if locally effective, would cause the current to seek a different avenue of exit, and so merely transfer the point of corrosion. A determination at such places of the direction of the current, whether from or to the rail, would show whether or not a non-conducting covering would be effective. Incidentally, the adoption of insulation at the current's point of departure would increase the resistance of the mains and so decrease the proportion of current carried, but complete relief by the plan suggested would require encasing of the entire distributing system, and as a final curative it may be dismissed as impracticable.

The same reasoning applies to the method adopted on certain lines of water pipe in Los Angeles, which were laid in conduits filled with sawdust, and also to the use which has elsewhere been made of a covering of pitch, kept in place by boxing of convenient form. All these protectives are too costly for general adoption, and no partial installation of any of them would wholly cure the trouble. * * *

In the earlier days of the "broomstick trains," the practice as to current direction was not as uniform as it generally is now, for in some plants the dynamos were run with the positive pole to the trolley wire, and some with the negative. In the latter cases, electrolytic effects were produced along the entire line wherever the current would find a ready path from pipes to rails, so that locating the injuries was a much more difficult task. As the car motors take current either way, however, reversing the current's

direction was an easy matter—especially in places where but one electric road is operating—and has been very generally done. The liability to corrosion is thus brought to within a narrower range, and largely localized in the neighborhood of the power-house.

Most prominent in point of number among the remedial devices adopted by the railroad companies are those for securing additional electrical contact at the bonds, and obtaining a bond conductivity approximately equal to that of the rail itself. The necessity of greater attention to this latter point is shown in the tables which have been published of relative conductive areas of the several sizes of rails and bonds in use; it has been customary to bond 56-pound rails, for instance, with No. 6 B. W. G. copper wire, whose relative conductivity is but one-twentieth as great. The use of the customary sizes of supplementary wires between the rails is by this comparison shown to be equally ridiculous and ineffective; one writer remarks that it is "laying a 12 inch water main and then putting a one-half inch pipe alongside to help it out," and it has been well said that the weight of copper now used in supplementary ground wires would be much better employed in the form of heavier bonds. * * *

The use of the "three-wire system" on electric roads has been advocated by Mr. W. Nelson Smith as a deterrent of electrolytic corrosion, and has been in operation at Portland, Or., for the past two years, with reported success. In its application for this purpose on a double-track road, the trolley wire above one track serves as the positive, the other as the negative, and the rails and earth as the neutral wire. There may be a potential difference from earth of 500 volts to each trolley wire, and of 1000 volts between them. The rails or neutral wire merely carry the current required by the difference in load on the two sides of the line, which is only considerable when cars are starting out or going in, and in the morning and evening business and home travel, or in cases of "hunching." The difficulties in overhead construction and insulation are increased, but it is said that only one-fourth to one-half the overhead copper is required as for a two-wire all-copper system, such as the double trolley.

A common practice is to bury at certain points on the car line old car wheels, rails, or other forms of plates to collect the ground currents connected by supplementary wires to the power stations. But instances are known where such supplementaries have been used of so great length and consequent resistance, that instead of carrying the current back to the dynamos, they were found by test to be actually positive to the earth. Their insufficiency is more explicitly shown in the experiments of Mr. J. D. Rastron, Chief Engineer Union Railway Company, Chester, Pa., whose tests showed in one instance that the track and ground supplementary wires were carrying 235.5 amperes of current, the city water mains 12.8 amperes, and the plates, though connected with an unquestionably thorough ground in a creek, but 0.5 ampere. This was doubtless a case with exceptionally unfavorable conditions; but even under propitious circumstances, no great proportion of the current could be expected to reach the isolated ground plates, of relatively small earth contact, as compared with the quantity following the long and heavy lines of pipe so widely to be encountered by earth currents.

Recognizing that the currents must follow the main pipes to some extent under existing conditions of railway practice, and that the injurious effects are produced at their points of leaving, the water department in Cambridge, Mass., has had heavy copper wires attached to the water mains and carried to the negative generator terminals of the electric roads, that the currents collected by the mains might leave them by a metallic circuit. The water pipes were also connected to the rails, and the water and gas services wired together within the cellars along the route of the road; intentional use thus being made of the pipes as conductors. In Milwaukee, the railway company connected its rails to the fire hydrants, but provided no means for the departure of the current until prevailed upon to supply an attachment near the power station. Elsewhere it has been proposed to run feeders to the power houses from the mains in various sections of the city, but not to connect the mains directly to the rails; in other words, to employ the mains, but only as a huge system of collecting ground-plates.

Of the three grades of this arrangement, the last is preferable, but even that is by no means desirable, for it serves to increase the conductive power of the pipes and so invites the approach of currents; and while no especial harm might be done to a perfectly tight water main so wired, a pipe having leaks or loose joints, or a gas main with cemented bells, would be speedily affected injuriously. Nor should the suggested attachment to water mains alone be permitted without protest by gas companies, for if the water mains be made better conductors than before, more tendency will be manifested by such vagrant currents as may

have reached the gas pipes to leave them and enter the water mains, so spreading the likelihood and locality of electrolyzation.

Mr. I. H. Farnham, in a recent paper before the Institute of Electrical Engineers, gives the following description of still another plan:

"Prof. Elihu Thomson suggested placing motor-generators along the railway line wherever the cables and pipes are found to be in danger, to be operated by the railway power current, the secondary current developed by these generators to be utilized to lower the potential in the cables and pipes to zero with respect to the surrounding earth or rails. The suggestion included means for automatically starting and stopping the generators, as cables might become positive or negative to the rails. The motor-generators would, so to speak, pump the current out of the cables and force it into the rails whenever the potential of the former should rise above zero. This plan has not yet been put into operation so far as I am aware."

Among the devices described in the foregoing paragraphs are most of those which have been adopted to any extent by the railways as preventives of electrolytic action. As deterrents or diminishers, many of them assist, but not one fulfills the requirement of complete protection, nor can any system do so which uses the rails to any appreciable degree as conductors. On many of the lines of electric railways—perhaps on most of those within the cities—the rails lie parallel for long distances with lines of gas and water mains, much better conductors than equal columns of earth, and in cases of poor bonding often exceeding in conductivity even the rails themselves. Separated from the latter only by a strip of earth, more or less moist, the capacity of the rails to conduct all the current is subject to the conductive law of inverse resistances, for so long as the rails offer any resistance at all, some current will also follow the lines of higher resistance. The pipes will be called upon to bear a portion of the current under the most favorable circumstances, and, so doing, will be injured, for it has been shown by experiment under conditions identical with those existing in practice that electrolytic action may occur with differences of potential of 0.5 volt.

It has been claimed that the perfection of the alternating current motor in its application to street railway work would solve the problem of electrolysis, and the advantages of this system for long-distance power transmission have caused it to be considered for adoption on the Erie Canal trolley line. But though faith in the inability of alternating currents to exert electrolytic effects is not universal, we need not consider the pros and cons, for the motor in satisfactory form is not yet on the market, and the immediate solution of the question before us must be sought apart from its improvement.

A system which many large roads are now adopting as a means of decreasing their current leakage is that of using insulated track feeders designed to carry the entire current, joined to the rails at short intervals, each 400 or 500 feet, for instance. The rails are thus employed as conductors only between the feeder junctions, and the liability of leaking currents is very much reduced. The system is certainly a step in advance of anything we have yet considered; and having been adopted in Boston, Brooklyn, Cleveland, etc., we should soon bear it, by its use, destruction of the pipes is wholly avoided. * * *

Another class of injuries from the same general source as the electrolytic has been brought to the attention of your committee, namely, arc effects caused by short interruptions in the continuity of the metallic lines made to serve as conductors. Of this character were the cases in Boston, where the yarn was ignited in the bells of pipes which were being laid, and in Indianapolis, where the leaking current followed down a trolley pole and burned a hole in the natural-gas main close by, the escaping gas from which returned through the hollow pole and was lit at its top, destroying a considerable extent of the neighboring overhead wires. There the railway's system was the greater sufferer; but such poetic justice as this seldom follows. The solution of the electrolytic question, however, will largely carry with it the prevention of this class of effects, so that they need not be specially considered.

In detailing the several plans which have been tried or suggested for the abatement of the troubles which we are considering, your committee have endeavored to show warrant for their belief that the full remedy for the difficulty cannot be applied by those who are suffering from its effects, but is attainable by the railway companies, and must of necessity rest with them. That they will endeavor, if assuming the cost of the work, to adopt the cheapest method which offers a measure of protection to the pipes, is of course to be expected. But their responsibility and liability once fixed, we may insist upon their adoption of an absolute preventive, or their rendering of adequate indemnity for all electrolytic injuries to our systems.

The regulations adopted by the special joint committee

of the two English houses of Parliament, to be applied to electric traction companies installing their systems under the jurisdiction of the Board of Trade, are much more stringent than any which have been proposed in this country. Our object is to secure the proper protection from injury by systems already in operation, of a quasi-public nature and occupying the streets like ourselves, whose extension we would not seek to hinder or whose methods to question except as they entail danger or expense upon us to our exercise of rights and duties equally important with theirs, and materially antedating them in introduction.

Mr. H. H. Humphreys, in his paper on this subject before the Electric Club of St. Louis, remarks:

The courts have decided, in numerous telephone cases, that the street railways have a right to the use of the earth as well as other people; but the question whether they would allow the railroad companies to use the gas and water pipes, and by using them, use them up, has never been decided that I know of.

The Supreme Court of Tennessee has held, however, in an issue on behalf of a telephone company whose operation was affected by induction at the advent of electric traction, that it was not the legal duty of the telephone company to protect itself, but that it devolved upon the railway company to refrain from causing injury.

In several places where the water supply is conducted by a department of the municipal corporation, the commissioners have notified the railway managers that their companies would be held accountable for damages to pipes, and that the supply of water to their power stations was liable to interruptions unless the source of danger was removed. With the realization of the actuality and extent of the danger, water companies and departments all over the country are taking steps toward obtaining an understanding with the railways causing the trouble, and especially in the cases of such cities as include water supply as a function of the municipality, the gas companies cannot do better than co-operate with them for mutual protection. If personal and corporate interviews and correspondence with the railway people fail of their object, the courts may be appealed to for restraining orders. Application for a stay of the injunction would doubtless be made on behalf of the railway, and the equity of the question would then be brought to a hearing. But meantime the deterioration of the pipes would be progressing; and even with the installation of a double trolley system decided upon by the railways, some time would elapse before it would be completed. Your committee would then recommend the insulation of all renewed pipes in places found to be injured, the drain tile casing being probably the best for services and small mains, and boxing filled with pitch for larger mains, and the use of cement joints in any new main being laid. The detection of leaks and the determination of unaccounted-for output are so much easier to gas than to water companies that any marked losses on the gas-pipe lines at least are likely to be signalized in some manner readily recognized.

In justice to the railway companies, it must be said that they are fully alive to the serious character of the problem which confronts them, and are equally anxious with ourselves to remedy and avert the trouble. They have a vital interest in the matter apart from the liability under which they rest for damages to other underground metallic systems, for the solution of the electrolytic question means to them a marked reduction in operating expenses, greater efficiency of the motors, and relief from the menace of interrupted water supply. But they naturally hesitate to accede immediately to demands which would involve the reconstruction of so considerable a portion of their plants; and as one of the electrical journals states, while the double trolley would remove all cause for complaint, the railway companies will exhaust every other means before going to the expense which that remedy would involve. But with recognition of the justice of claims for indemnity for injuries to our distributing lines, and a clear demonstration, such as is now being afforded in several directions, of the futility of any half-way measures, we think that the street railway world will eventually concede the superiority of the double trolley and its kindred systems.

Your committee then summarize their findings as follows:

First. Electrolysis from the grounded currents of electric roads is rapidly injuring gas and water pipes, and it is admitted by street railway people that the injury does proceed from their operations.

Second. Complete relief from its action cannot be reached by any device applicable by those injured, but is attainable by certain changes in the electric railways.

Third. The gas and water interest should unite in demands for remedial measures which shall secure the adoption of systems undoubtedly effective, and which will thereby avoid a revival of the question a few years hence.

Fourth. Pending the discussion or completion of the relieving systems, the pipes should be protected at exposed points, at which the policy of increasing the resistance by insulation should be followed rather than that of increasing the conductivity by wiring.

Distributing Cold.

The distribution of light, heat, water, power, and even human speech, from a central station has been an accomplished fact so long that it attracts no attention. The artificial production of cold, as illustrated in various chemical and domestic operations and in ice factories, is also a familiar process; but the successful distribution of cold from a central station is so recent as to be known only to a few. This is now accomplished over large areas. Cold is but the absence of heat; it is therefore only necessary to cause the heat in any space to disappear to produce a low temperature, or cold. The removal of heat must, then, be the principle involved in all refrigeration.

The production of cold at widely different places from a central station, accordingly, does not differ in principle from its production in an ice factory. While this is true, the engineering difficulties in the pipe-line distribution of cold were very great. It has been unsuccessfully attempted at various places, including London, New York, Boston and Paris, but is now in successful operation in Denver and St. Louis.

In these plants the agents for producing cold is liquid ammonia. This substance, says a writer in the *Cosmopolitan*, is liquefied at the central station and transmitted through iron pipes, under a pressure of 150 pounds to the square inch, to the places to be cooled. At these places the liquid ammonia flows through an adjustable opening in a small valve into one end of an expansion or cooling coil. The other end of this coil is connected with a return pipe, leading back to the station. The boiling point of liquid ammonia, under atmospheric pressure, is about 30 degrees below zero, so that any temperature above this will boil it away very rapidly. This boiling away, or evaporation of the liquid ammonia in the expansion coil, cools the surrounding space and the temperature desired is obtained by regulating the rate at which the ammonia escapes from the main. A constant suction is kept up in the return pipes, so that the vapor of ammonia returns to the central station for repeated use.

In this process a liquid fills the outgoing pipes and vapor the return pipes, which is just the reverse of the steam-heating process, where vapor fills the outgoing pipes and liquid flows in the return pipes. In steam-heating from a central station, there is much loss by radiation from the mains; in the refrigerating process there is no corresponding loss, as the liquid ammonia is passed through the mains at ordinary temperatures.

The system described admits of many applications, the most ordinary and important of which at present are the cooling of storage boxes for hotels, restaurants, saloons, butchers and butter-houses, and in enabling hotels and cafes to make their own ice; in cooling water for large stores and factories, and in cooling soda-water fountains. Among the luxurious applications may be mentioned the cooling of summer cafes and dining-rooms to any desired temperature. In St. Louis 10 or 15 degrees between the inside and outside temperatures were found most satisfactory. For this room-cooling the same pipes used as a cooling coil in summer are used as a steam radiator in winter.

The area that can be supplied with cold from a single station is about the same as can be supplied with illuminating gas. This new industry can never become as general as those mentioned in the beginning of this note, for "keeping cool" is in many cases a luxury rather than a necessity.

State Mining Bureau.

It strikes us that not enough attention is paid to this most important bureau. Half of our people don't even know where this institution is located, further than it is somewhere in San Francisco. If every person who visited the Midwinter Fair had also visited the State Mining Exhibit, they would have learned considerable about the mines in the various counties, more, we dare say, than they could learn at the fair. At the fair the mining counties put forth their best foot and boomed their exhibit way up; at the State Mining Exhibit the exhibits are permanent (so to speak). No gaudy rock is shown here—nothing but the real thing and things as they are. The State Mineralogist, J. J. Crawford, has a corps of efficient assistants who are always both willing and anxious to show visitors through the building. They take pride in having visitors, for it shows that the people in general take an interest in mining matters.

We would like to see the papers in all the mining counties take up and agitate this most important matter, and feel sure it would redound to the everlasting benefit of the miners. Remember that the State Mining Bureau is located in Pioneer hall, No. 24 Fourth street, below Market, San Francisco, and don't fail to call there when next in the city. The admission is absolutely free.—Downville Messenger.

Scientific Progress.

Origin of Petroleum.

Mr. J. J. Jahn, in an article, "Zur Frage über die Bildung des Erdöls," states that in his study of the Silurian rocks of Bohemia he found in a dolomite of the Pridoli valley that the hollow portions of fossils—such as the chambers of *Orthoceras*, or the space enclosed by the two valves of a *Lamella*—often contained a sort of nucleus of little lumps of anthracite or drops of petroleum (sometimes both substances), while the rest of the drusy hollow was taken up by calcite or dolomite crystals. The same occurrence is noticeable in the limestones near Stolba, and not only are the anthracite lumps and petroleum found in immediate connection with the fossils, but they, as well as mineral wax, occur disseminated in the mass of the rock itself. These substances, whether in intimate connection with marine shells, or apart from them, are evidently the result of the decomposition of the animal organisms which, ages ago, were buried in the calcareous mud of the Silurian sea.

The author considers that his observations herein confirm the views of Prof. C. Engler, who attributes the origin of petroleum to animal organic remains, and has succeeded in artificially producing that substance and its by-products from animal matter. It is now seen that the idea that a large quantity of coal necessarily implies a paucity of petroleum, or the abundance of the latter, the scarcity of the former, in any particular locality, is erroneous. Wherever the Silurian limestones of Bohemia contain anthracite, there, too, either petroleum or bitumen is found; and one is impelled to conclude that the formation of coal by the decomposition of vegetable matter went on concurrently with the formation of petroleum by the decomposition of animal matter. The author thinks, moreover, that some anthracite may well be of animal origin; it may arise, perhaps, from the decomposition of masses of the chitinous skeletons of Graptolites.

The conditions of temperature and pressure which Prof. Engler found necessary in his experimental manufacture of petroleum probably obtain in nature as a result of the crumpling and crushing of the earth's crust, and of the eruptions of igneous rock which not seldom accompany these phenomena. It is a striking fact in this connection that the Stolba limestones become more dolomitized as they approach the neighboring eruptive rock, diabase.—Jahrbuch der K. K. geologischen Reichsanstalt, Vienna.

Chemical Change from Mechanical Energy.

H. Carey Lea, the scientist, is at work trying to produce chemical change from mechanical energy. Light has the effect of darkening and reducing or disintegrating certain salts of silver bromides and iodides. Mr. Lea finds that he can produce similar results merely by compression. In some of his attempts he exerted a pressure of 1,000,000 pounds to the square inch.

From a commercial point of view this is a valueless expedient; but a principle has thus been established. Now, what the physicists would like to know is whether that operation can be reversed and chemical change can be made to yield mechanical force directly. In a primary or secondary battery chemical action produces electricity, and this can then be converted into mechanical force. So, too, by burning we get heat, and then can turn heat into power. But what certain investigators are trying to ascertain is whether the intermediate stage cannot be dispensed with, and if so, how. The particular object in view, or at least one important aim in this inquiry, is the discovery of a way to obtain from coal something like the full amount of energy that is stored up in that familiar compound. It has been as-

serted that by our best methods of combustion in connection with a steam boiler and engine only about one-tenth of the work is extracted which the sun placed on deposit therein away back in the vegetative processes of the carboniferous era. A tremendous revolution in the methods and cost of all manufacturing operations and in propelling cars and ships would be wrought if ever a secret of this sort were wrung from Nature. And her mysteries, it is safe to say, are not yet all unravelled.

The Electric Utilization of Niagara.

The necessity for having manufacturing establishments located where the water wheels are has greatly limited the use of water power. Now that electric energy can be transmitted to great distances on wires, one may have his source of power with a dynamo where the water power chances to be, and his factory with its motor where it is economically best to put it, and these places may be many miles apart, and many rivers may be made serviceable which have hitherto been but a waste of power.

One of the largest of these is the Niagara river and falls, where about 18,000,000 cubic feet of water flows per minute through a descent of more than 300 feet, including both falls and rapids. This represents something like 10,000,000-horse power. For the utilization of a portion of this a company has constructed a tunnel about a mile and a half long, running under the town of Niagara, from the river above the falls to a point just beyond the foot-bridge below the falls and a few feet from the surface of the river, giving nearly 200 feet for a head of water. The capacity of this plant is 100,000-horse power, and there are to be many turbines, some of them 5000-horse power, for driving 5000-horse power alternating dynamos intended to maintain a current at 2000 volts.

Manufacturing establishments in the immediate vicinity will probably have wires connected directly to the dynamos, but factories at a distance of ten or more miles will have the voltage raised by transformers to 10,000 volts or more, and again transformed to lower voltage where the power is to be utilized. This process is to save in cost of conductors, for a given amount of electrical energy of high voltage requires a smaller wire than if the voltage is low. A number ten copper wire, which is about an eighth of an inch in diameter, which will conduct, say, 30-horse power at 1000 volts, will conduct 100-horse power at 4000-volts. It is expected, says a writer in the *Cosmopolitan*, that most of this power will be used for motor work rather than in lighting, and Niagara companies have been organized in several cities and towns about some of them at the distance of 100 miles or more, with the probability that ultimately some of the energy may reach even New York City. It seems likely that the region about Niagara will soon become a great industrial center, where all sorts of mechanical enterprises will be grouped, because power can be had cheaper than elsewhere. There are many questions concerning the economical distribution of electrical energy that will be settled by this Niagara plant, and engineers are watching the developments with great interest. After these are settled, by experience, water power in places now inaccessible for manufacturing purposes will suddenly become valuable properties for electrical power stations. No one need feel apprehensive that Niagara falls will be seriously affected by this seemingly large draught upon its water supply. In reality it represents but about one-fortieth of the bulk of the water of the river, and several such power plants might be established there without diminishing the flow appreciably.

THOMAS KELLY of Keokuk, Ia., writes that evidences of a pre-glacial river have been found, which in earlier ages drained

Lake Michigan westward into what is now the Mississippi river. Some of the places where this river ran are covered by nearly 200 feet of deposit, but the silt which occupies the river's bed is black and contains shells which show remains of earlier animal life, probably before men lived on this planet.

M. LOUIS BOUTAN has succeeded in taking some beautiful photographs of the bottom of the sea by the aid of a newly invented lamp for burning magnesium powder under the water. He first descends to the bottom and selects his views, next has his apparatus lowered to him, then arranges the same for several flashes, enabling him to take as many successive pictures.

THE great Pitch lake of Trinidad covers 99 acres and contains millions of tons of so-called pitch. This is in reality a mixture of asphalt and oil, which is continually oozing up through cracks and crevices beneath the pressure of the strata of rock above.

THE cylinder head of a Connecticut locomotive blew out while at full speed. The train's momentum carried it to the station five miles away without a pound of steam.

Diplomas awarded. To begin students need only to know how to read and write. Send for FREE Circular of Information, stating the subject you think of studying, to The Correspondence School of Mechanics and Industrial Sciences, Scranton, Pa.

4000 STUDENTS.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of invention in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING and SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantage for Pacific Coast inventors are far superior. Advice and Outlines free.

DEWEY & CO., PATENT AGENTS,

220 Market St., Elevator, 12 Front St., S. F. TELEPHONE No. 658.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulas as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1890.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed with facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$8. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

GEO. E. BELMOR,

OF THE BELMOR BOILER WORKS,

Has Removed from 210 Mission St. to 52, 54 and 56 Hixson St., bet. 4th and 5th.

(To the old H. W. Rice Machine Works.)

Mechanical Progress.

The World's Gold Supply.

The most eminent living writers on the precious metals, Suess and Soetbeer, have recently published what the New York *Telegram* calls a very alarming statement. It is to the effect that the total amount of gold dug out of the earth annually suffices only to supply the present demand for that valuable substance for use in the arts. Not a bit of the new product of the mines is available for coinage. Trinket use and waste in manufacture exhaust the whole yield. If this is correct, then gold must vanish from circulation before long, because the output of the gold mines of the world is diminishing rather than increasing, and there are few fields left to explore. But Uncle Sam's metallurgists say that it is not so. The writers quoted fail to consider the fact that the gold employed in the arts is utilized over and over again. It goes through a sort of cycle. Articles of jewelry often disappear, but are seldom lost. When, through accident, they pass out of the possession of the well-to-do, they go to the poor and sharp-eyed, who sell or pawn them. Some jewelry is lost by fire and some in the sea, and these losses are absolute and hopeless; but jewelry otherwise is certain, practically, all of it, to find its way, sooner or later, to the pawn shops or into hands of dealers in old gold. Thus it is melted up eventually and reappears again in other shapes. This is what is termed the "invariable supply" of that metal.

There are a number of unavoidable causes of loss of gold. The first and most important of these is by abrasion. Jewelry loses much weight in that way, especially rings, which are usually eighteen karat and are worn rapidly. Coins suffer much less, but still considerably from wear. All gold leaf is a total loss to the gold stock of the world. Where used for decorative purposes it is never recovered. It is not employed for filling teeth nearly as much as formerly, "porous gold" being substituted. But, of course, the gold utilized for filling teeth is a total loss, and in the aggregate it is enormous in quantity. If it be supposed that the average dweller in cities of this country has 50 cents' worth of gold in his or her mouth, which is placing the figure very low, it will be seen how great is the waste in this form. Each succeeding generation takes so many millions of dollars' worth of the metal from the world's stock in this way. Some gold is lost in remelting, though all possible means be taken to reduce it to the lowest possible figure. Not only are the floors swept and the dirt treated for the recovery of the yellow substance, but the wooden planks are burned eventually with the same object. Even the shoes of each man who works with the metal are subjected to the chemistry of fire, yielding a small "button" of the precious metal.

To Penetrate Iron Shutters.

Ever since iron shutters and doors have been used upon warehouses, factories and other buildings to protect their valuable contents against damage and destruction by fire, the problem of effectively and immediately reaching a fire behind those shutters and doors has baffled the fire departments, and at the present time they have nothing more effective than axes and bars, or to wait for the shutters to become so hot that a stream of water thrown on them will cause them to warp or crack open. In the meantime, the goods protected have furnished fuel for the fire.

There are drawbacks to cutting holes in the roof in order to get access to the flames, one of them being that a draft is thus opened, which promotes combustion and increases the peril.

The water introduced through the open-

ing generally fails to reach the fire, the fireman being unable to see the point at which it should be applied.

These iron doors and shutters frequently

THE APPARATUS IN USE.

have a hole large enough, near a bolt, to admit a hand. Sparks are liable to enter this opening and to prevent this, some shutters having a swinging disk covering the hole. Another kind of shutter is provided with an automatic latch that can be released by a heavy blow.

The fatal objection against shutters with

FIG. 1.—A, Fire hose connected to engine or hydrant. B, Nozzle. C, Water pressure valve. D, Coupling to connect the nozzle. E, Water motor. F, Exhaust. G, Flexible shaft. H, Cutting tool.

any of these appliances is that they are not burglar-proof.

The law calls for shutters provided with openings that bars may be inserted, but these are so evidently insecure against sparks from neighboring buildings and the attack of the burglar that they will not be used when it can be avoided.

John G. Von Hofe of New York has invented a simple mechanical device, which utilizes the hydraulic pressure of the water in the hose used by the firemen at the fire.

This apparatus is attached to the end of the hose and in a moment the fireman is able to pierce the iron shutter or door or to cut away the iron bars and throw water on the fire immediately.

This arrangement is easily carried on the fire truck or on the patrol wagon.

The apparatus weighs about 40 pounds, and with a pressure of 75 pounds it attains one-half horse power, and makes about 1200 revolutions per minute.

A pressure regulating valve is located between the motor and the fire hose, and a

novel arrangement in the handle stops or starts the tool while the shaft is spinning.

The manner of operation is briefly described as follows: When fire occurs in a building protected by iron shutters and with all means of access cut off, the fireman erects a ladder to the window, hangs the apparatus on his shoulder and ascends.

When in position he hangs the apparatus on the ladder by a snap-hook, securing it firmly by a strap.

The hose is then connected with the apparatus; the fireman grasps the handle and the water is turned on.

The fireman in a moment cuts away the bars or pierces the shutter; then detaching the hose, pours water on the flames.

The following will describe the figures in detail:

Fig. 1 is a general view of the apparatus consisting of a motor attached to a flexible shaft and a set of interchangeable tools adjusted to this shaft.

FIG. 2.—G, Flexible shaft. H, Cutting drill. I, Casing for cutting drill. J, Spring to adjust the casing. K, Handle. L, End of flexible shaft. M, Interchangeable sleeve. N, Sleeve fasteners.

FIG. 3.—M, Handle with sleeve. O, Spindle with cam for reciprocating movement. P, Double-edge saw.

Fig. 2 shows one form of drill, the center point projecting beyond the outer teeth enveloped in a casing, which protects the fireman from injury.

When this drill is connected with the shaft, and held to a metallic shutter, the central point pierces a hole first, and as the handle is pressed forward, the casing or guard rests itself against the shutter, causing the cutter to present itself squarely to the surface.

As the handle is forced forward, the spring back of the guard allows it to recede; at the same time the circular set of teeth move forward with 1200 revolutions a minute, and in a very short time a hole large enough to admit a hand is made. The hose is then disconnected, and, should the fire be too close to allow opening the shutter, the hose is put through and the water poured on the fire.

Fig. 3 shows a saw with teeth on either edge for cutting iron bars or grating. The saw has a reciprocating movement from a cam within the handle.

This instrument is used where the building is guarded by iron bars or grating, but can be instantly removed for the circular cutter before described.

Batteries for Use With Telephones.

Some confusion prevails in the public mind regarding the use of batteries in connection with telephones. In operating these instruments electricity is used for two purposes, to ring a call-bell and to convey speech. Customers, direct or indirect, of the Bell Company operate the call with a magnetic device, a diminutive dynamo, turned with a crank, and hence no battery is needed. But in some of the other outfits, which are sold outright and not rented, this service is performed with what is called an "open circuit" primary battery, either wet or dry, the number and kind of cells depending on the length of the line and the frequency of use. A storage or secondary battery is also available. In a building already wired for incandescent lighting, such a call or door bell could be operated by putting it into a loop with a single lamp to regulate the amount of current; but this is not customary. The way in which electricity for talking over a wire is generated depends on the transmitter used. If this be the Blake, or "variable contact," device, then some sort of an open circuit cell, probably a strong one like the Leclanche or the "bichromate," is commonly employed. This is inclosed in a box on the same board with the other fixtures. If, however, one has instead of the carbon transmitter a "magneto," either exactly like or working on the same principle as the receiving instrument (on which Bell's patent expired last January), no battery is required for conversation. Buyers of such outfits, though, should remember that in talking for more than a few hundred yards an extra strong magnet, instead of the ordinary one, is desirable in the transmitter. It will thus be seen that with some equipments a battery is used for the call-bell only; in others for conveying speech only. But with certain instruments a battery may be dispensed with altogether.

A word or two here about batteries. In certain kinds of work, like electroplating, the dissolution of substances in order to produce metals, or telegraphing, a continuous current is necessary; and nowadays, where such work is done on a large scale, it is found more advantageous to derive it from a dynamo than from a battery, which depends on the chemical action of one set of substances (generally in liquid form) upon another set. Still, batteries especially designed for such heavy work are yet in use, and these are known as closed-circuit batteries. In an open-circuit battery the destruction of acids upon the metal plates or rods, by which the current is produced, goes on only during the few seconds or minutes of actual service, while a button is being pushed or while an automatic switch is closed by taking down the 'phone from its hook. Hence different materials are used in such batteries, although they work on exactly the same principle as the others. A great variety of these are known to electricians, the metals and solutions and mechanical construction differing in detail. An important subdivision of such apparatus includes what are known as "dry" batteries, of which several are in the market. In these there is no fluid to slop over and make trouble in case of accident, the chemicals deriving whatever moisture they require from a paste or semi-solid filling, confined by hermetically sealing the jar containing it. Even intermittent service, such as open-circuit batteries are called on to perform, varies in frequency and degree, and for light work dry batteries, which are usually cheaper than wet ones, will often last for months or even a year, requiring absolutely no notice. The best open-circuit batteries of the other class, however, need but little care—filling up with water once a month perhaps, renewal of zinc or copper plate every two or three months, or some other trifling or inex-

pensive attention. Storage batteries, in which electricity already manufactured is accumulated, will of course do all the work; but it is necessary to send them out to be charged every now and then, and it is not always easy to arrange for this. Hence primary batteries are generally preferred to secondaries.

Batteries constructed especially for only occasional use, it must be remembered, are liable to lose in efficiency if drawn on continuously for half an hour or so, and require long intervals of rest to keep in good condition. This temporary paralysis is different from the final exhaustion or death of the apparatus, in its nature, but the possibility must be kept in mind.

How Far Can Electricity Be Carried?

The attempt to convey, in the form of electricity, power from Niagara on a large scale, over long distances, is exceptionally interesting, not merely because of the capacity of the cataract itself, but because in many ways it is a great experiment. Except for a certain exhibition plant, transmitting power from Lauffen to Frankfurt (Germany) in 1891 (100 miles), no practical work of this sort has been done for a greater distance than about 20 or 25 miles; and the Lauffen-Frankfurt venture could hardly be conducted cheaply enough to be a success commercially, although it was such from an engineering point of view. Hence a discussion of the possibilities of Niagara by two well known and presumably disinterested electricians, Edward J. Houston and E. A. Kennelly, in the *Electrical Engineer*, recently, deserves attention.

These experts at the outset slightly amend the estimate of Prof. Forbes, consulting engineer of the Cataract Construction Company, regarding the hydraulic works (intake, canal, wheelpit, turbines, power house and tailrace tunnel), so as to make the cost of one-horse power delivered by the wheels about \$3, or of one kilowatt \$4. Amperes (or volume) multiplied into volts (or pressure) gives watts, and .736 of these make a horse power. But electricians prefer to figure by thousand watts, or kilowatts, each of which is equal to 1.359-horse power. Calculations are here made on a basis of nearly 120,000-horse power, which the present works are expected to develop. Perhaps 110,000 is nearer the company's own estimate, though. It is also assumed that the voltage employed for transmission will be 50,000, as previously announced. Messrs. Houston and Kennelly next figure on the cost of dynamos or generators, transformers at both ends of the line, motors to convert the current back into power, necessary line (bare overhead wires being deemed safe), superintendence and operating expenses, besides allowing ten per cent for interest, depreciation and repairs. Another item is the loss of electricity in transmission, and to meet this they regard 1.174 kilowatts necessary at the turbine shaft at Niagara to enable the motor to deliver exactly one in Buffalo (15 miles away), 1.588 to give one in Syracuse (164 miles off), and 2.048 for one in Albany (330 miles distant). The only other variable factor is length, and hence cost of line, wire, poles and insulators.

The amount of power delivered in each place has to be considered, however, and in this computation it is assumed that Buffalo receives 22,500 kilowatts, Syracuse 7500, Schenectady 7500, Albany 15,000, and intermediate points 15,000, or 67,500 in all. This is equal to about 92,000-horse power, the net product of that 110,000-horse power plant. Now, if the full amount be delivered in each case, the estimated cost would be \$10.69 per kilowatt annually in Buffalo, \$17.22 in Syracuse and \$22.14 in Albany. But, as the average delivery would probably be only 60 per cent of the maximum load, the whole cost should be assessed on that proportion of power, making the corrected figures for a kilowatt \$17.82 a year for

Buffalo, \$28.70 for Syracuse, and \$36.90 for Albany. Averaging it up for all points, though, the rate is made \$16.72 for the maximum load and \$27.87 on the basis of a 60 per cent mean consumption. According to Emery's tables (widely accepted as a standard), steam generated in large amounts by coal costing \$3 a ton cost for 308 days a year and 10 hours a day \$33.88 per kilowatt annually, or for 365 days of 20 hours each \$59.56. But the majority of factories need power only about 10 hours a day. Messrs. Houston and Kennelly conclude, therefore, that "the power of Niagara Falls can be transmitted to a radius of 200 miles cheaper than it can be produced at any point within that range by steam engines of the most economical type, with coal at \$3 per ton; that Niagara power can maintain at Albany a large day and night output cheaper than steam engine at Albany can develop it; but that for power taken at Albany for ten hours per diem the best steam engines have somewhat the advantage over Niagara, unless exceptionally favorable conditions of load could be secured for Niagara power." They further remark, concerning the 200-mile limit, that "it might be commercially advantageous for such a large water power to undersell large steam powers at twice this distance with no profit, in order to reduce the general expense upon delivery nearer home."

Making Visible Lines of Electric Force.

Herr Bruno Kolbe thus describes an experiment for making visible lines of electric force: Into a flat cylindrical vessel pour anhydrous oil of turpentine to a depth of two cm., and add some sulphate of quinine. Attach to the rim of the vessel two wire spirals, adjusted so that the two small metallic balls at their ends dip into the turpentine. Stir the quinine with a glass rod so as to distribute it evenly, and place the vessel on a black cardboard. The two wires are then joined to the terminals of an influence machine and turned very slowly, and the white crystals group themselves at once so as to form beautiful curves, representing the "lines of electric force."—Invention, London.

Practical Information.

Spiders' Webs as Scientific Instruments

The astronomers of the Naval Observatory at Washington have sought all over the world for spiders' webs. Such gossamer filaments spun by industrious arachnids are utilized in telescopes for cross lines extended at right angles with each other across the field of view, so as to divide the latter into mathematical spaces. Threads of cobwebs are employed for the purpose because they are wonderfully strong for their exceeding fineness, and also for the reason that they are not affected by moisture or temperature, neither expanding nor contracting under any conditions. Specimens were obtained from China by the directors of the observatory, because it was imagined that the large spider of that country would perhaps produce a particularly excellent quality of web.

However, it was found that the best web is spun by spiders of the United States, such as found in the neighborhood of Washington. Accordingly, expeditions are made early in June each year to get from the fences and barns thereabout cocoons of the big "turtle back" spiders. Each cocoon is composed of a single silken filament wound round and round, though there are apt to be some breaks in it where Mistress Spider left off work for a time. Attempts have been made to use the cocoons of spiders like those of silkworms, and exquisite fabrics have been manufactured from them. Unfortunately, it was found impossible to make the industry a commercial success, owing to

the combative inclination of these creatures. When kept together they will always gobble each other up in a short time, the final result being a single very large and fat spider and one cocoon.—The Optician.

Curious Effect of Changing Time.

The introduction of Middle European standard time throughout Germany had the effect of reducing considerably the amount of gas and electricity used for lighting purposes. Throughout a great part of Germany the time was advanced from 10 to 30 minutes. As business hours are of course regulated by the standard time, business now, while closing nominally at the same time as ever, closes actually from 10 to 30 minutes earlier than before and as much gas as is consumed in that time is saved. This deficiency is not made up by business beginning earlier in the morning, because most business begins so late as to require the aid of artificial light in the morning for only a short period in the year. Restaurants and cafes that close at midnight save from 10 to 30 minutes of artificial light. The reduction of electricity for lighting consumed in Hannover is calculated to be eight per cent, representing a reduction in the income of the company of 2000 marks per year. Figures for gas are only given for two small cities, Kiel and Brochum, which report the reduction of gas consumed in the last year to be 103,000 and 100,000 cubic meters respectively.

Reducing Cost of Mining.

One of the ways by which the Tennessee Coal, Iron and Railroad Company economizes in mining is shown by the system employed at its Whitwell collieries, in Marion county, Tenn. The mines are situated on the side of Cumberland mountain. There are three openings in the face of the mountain, and the coal is brought by means of tram cars to the head of a double-track incline at the central opening and there dumped into bins. From the bins, trip-cars, carrying five tons each and running in pairs on both ends of the cable, are filled. The incline is nearly a mile long and is controlled by drums at the top with powerful hand brakes and automatic fan governors. The use of powder in the mines is largely avoided by undermining in the day and allowing the settling of the roof to loosen the coal during the night. The mines are drained by siphons, so arranged as to be primed by one man without stoppage. So completely has the force of gravity been utilized that there is not a steam boiler on the work. The output of the mines is about 1000 tons per day.

The Value of Brevity.

In conversation with one of the leading lawyers of this town the other evening, our talk drifted upon the enormous fees sometimes paid to the members of that profession, and he cited an instance where a lawyer received a large retainer for the composition of only three words. Every one is familiar with the famous sign of the Reading railroad, "Stop, look and listen," which is placed on grade crossings along its lines, but comparatively few know the real significance of these few brief words. The rule of the roads, from a legal standpoint, is that a teamster or driver must stop, look and listen for an approaching train. Previous to the adoption of this sign the company used these words, "Beware of the engine and cars," followed by a series of injunctions that no man walking would have patience to read. There were several accidents which brought the company into court, and the opposing counsel claimed that these signs were not clear warning. McLeod went to Judge Paxson, who wrote the admirable sign now in use by that company, "Railroad crossing; stop, look and listen," receiving for this modest composition the sum of \$4780, a

trifle over \$796.66 a word. It can fairly lay claim to being the most expensive composition on record, and shows very forcibly the value of brevity.—Shenandoah Herald.

Sky Scrapers in Chicago.

It is a fact well known to the builders of the tall buildings called "sky scrapers" in Chicago that there is a constant and uneven motion going on throughout the whole structure, called by some molecular vibration, to an extent which can be measured with the naked eye. Girders will move an inch or more, and then come back into place. The causes of this movement are as yet entirely unknown, as are their extent and duration. Another peril which menaces this class of building is oxidation. The steel frames are inclosed in fire-proofing and beyond the reach of examination or the application of preservatives. The disintegration may be slow, but the day must come, so say good authorities, when the great buildings must succumb to rust and ruin.

FOREIGN PAPERS say that about 18,000,000 taels, or \$15,000,000, have been collected in China for the celebration of the sixtieth anniversary of the birth of the Dowager Empress of that country. This sum, however, is not considered sufficient, and efforts will be made to collect \$10,000,000 more. The celebration will be one of the most elaborate ever held in the Flowery Kingdom. The Dowager Empress is looked upon as the cleverest woman in China, and the virtual ruler of the country, as her son consults her upon every important question. He makes stated pilgrimages to the castle in which she lives to discuss public affairs with her.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes where he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt, will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Muffle in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Oupet; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, 31c. postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.
One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Installation of Electric Wires.

The number of casualties through the defective installation of electric wires are causing the insurance companies to make new conditions. The Hartford local board of five underwriters have issued the following instructions to those using electric lights:

All switches with wood or fibre bases to be placed with switches with porcelain or slate bases.

All flexible cords run on ceilings or wall must be removed.

Not more than one flexible cord must be taken from each rosette.

All lighting or power meters must have a slate back, or be placed on insulators so that the back of meter will be at least one and one-half inches from any inflammable material, and, when possible, meters should be placed on brick walls.

All direct current meters shall be wired with a one-half ampere fuse with the resistance and armature. This will prevent the resistance from becoming overheated when power wires are crossed with high tension currents.

All resistance boxes or rheostats must be equipped with metal or other non-combustible frames.

All fuses must have metal tips, having perfect electrical connection with the fusible part of the strip.

One Side of It.

There are more than 300,000 men employed in bituminous coal mining, most of whom are now on strike. They earn usually \$100,000,000, which is 68 per cent of the value of the coal at the mines. The mining companies have not been making any money lately, because so many mills and factories were closed that it has restricted the market for coal. The reduction of miners' wages was a shrewd move on the part of the companies. The managers expected that it would produce a strike. This was just what they wanted, in order to lessen production of coal and clear off surplus stocks. As soon as this is done the strike will end, and everybody will pay a little higher price for coal than he would if competition continued without restriction.—American Manufacturer.

The latest application of electricity is to

the business of starting horses in a running race. An Atlanta, Ga., man has invented an appliance for this purpose which runs on two rails, on either side of the path for the horses, and is joined by a rope across the race track breast high to the horses. It moves forward as the horses do, and by the pulling of a cord the rope separates in the middle and flies upward on two arms and the field is off. The starter sits on a platform on the inner side of the track, and moves with the field until he lets them go. If the thing works, it will be a great time-saver and largely do away with those tedious waits with which patrons of the turf are only too familiar.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 50 cents additional per volume.

GOLD EXTRACTION EXTRAORDINARY!

Two Improved Crawford Mills have treated about one thousand tons ore at the Columbia Mine, Moore County, N. C., capacity of each mill being over 10 tons daily, and the cost of wear and tear 20 cents per ton. On a formal trial run of 100 tons, 84 per cent of ore's value was cleaned up in gold, exclusive of some rich concentrates produced by mill. Three additional Crawford Mills have been added to plant at this mine.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 3, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

A BIG QUARTZ LEDGE.—*New Era*: A quartz ledge of an unusual exposed length has been discovered about three miles from Forbestown, and five locations of 1500 feet each have been made. The ledge is situated in parts of four sections, viz: 27, 28, 34 and 35, Township 20 N., Range 6 E. The ledge is wide and well defined and is said to prospect well.

The croppings in many places are 20 feet above the level of the ground. The exact width of the ledge is not yet known, but in some places where the croppings are broken down a width of 60 feet is shown. Several of the locators are doing development work upon their claims, and several assays of the ore have been made, showing an average of about \$20 to the ton. The ledge lies in such a position that each location can be worked by tunnels at a considerable depth, and good water power can be obtained from Sucker Run. Many of the locators are men of means, and we may expect to see the ledge fully prospected this summer, and, if possible, that a mill will be built by some of the locators this fall.

The ledge is without doubt the widest in the State. Messrs. Price & Co. have a shaft on their location down 30 feet, and are taking out some fine rock.

Although the ore is not high grade, its immense body makes the ledge valuable. It is not claimed that the rock is the richest, but its abundance and the ease and cheapness in which it can be mined and worked will make it very profitable.

Nevada.

Herald: The mill at the German mine, Washington, started up Saturday morning. Superintendent Goss has everything in good shape now, and will work the mine to its fullest capacity. The sawmill up at the Oak Tree (Eagle Bird) is running full blast, getting out timbers and lumber for the new mill and other buildings. The Oak Tree is grading for a new mill about twice as large as the present mill, and additional concentrators and other new machinery will be put in and the plant enlarged all around. This is probably the most important work now going on in the district. Superintendent Garland of the Rainbow is also preparing to put up a mill. The mine has none at present. The Rainbow is turning out well, and a mill of its own is now a necessity. So it will be put up this summer.

Shasta.

ALTOONA DEVELOPMENTS.—*Democrat*: Superintendent Cox, of the Altoona Quicksilver Mining Company was here Sunday and Monday with a company of 18 people—eight families—en route for the company quicksilver mine, 20 miles west of Castella. The men of the company are all experienced quicksilver miners, and go to work on the mine. They were fitted out with every means of comfort, and even had a brass band and orchestra with them.

The Altoona Company are making extensive developments on their property. Holt & Gregg have been given the contract to burn the brick and build the new boilers and furnaces, and Jim Holt leaves next Sunday morning with a crew of men to begin work. Gerald O'Shea has the contract for putting in all the freight for the company. The freight will all be shipped to Redding and from here hauled by team to the mine.

The company will shortly double the capacity of their works at Altoona and begin on a gigantic scale.

The Altoona is one of the oldest and most productive quicksilver mines in the State, and the new company intends to make it the largest producer in the country.

Development work on the Bully Hill mines at Copper City is progressing rapidly and with good results. Superintendent George Fitch has a force of five men at work at Bully Hill pushing through the tunnel, and it is expected they will uncover the ledge in a few days. The ledge is known to be there, as it was discovered many years ago, but was caved in on and lost.

Sierra.

SIERRA CITY MINES.—*Messenger*: The Bonanza gold mines will be running full blast as soon as the tramway is finished. They have two big ledges with a pay chute on both, and the mine will doubtless soon declare dividends to its stockholders. It will help out Sierra county immensely.

In the Chips mine a good pay chute has been discovered, and before long this mine will add its strength to Sierra's bullion-producers.

The Phoenix mine will soon change hands. The liens will all be paid off and the whole mine thoroughly prospected. An expert was up the other day to examine this mine for a San Francisco company which will doubtless take hold of it.

The Saddle Back mine, situated between the Buttes peaks, is another promising piece of property. A wagon road to the millsite is almost completed. This mine will be worked by connecting the mine and mill with a tramway over 6000 feet in length.

The old Martini mine, bonded by Oliver Sunderhans, has been working eight men all winter. The rock has been very hard all the way with the exception of probably fifty feet. There are two chances in this place—one for gravel and one for quartz. About forty years ago a company of Mexicans ran arrastras on the flat rock which was very rich.

Wm. Edwards, formerly foreman of the Sierra Buttes mine, is in town this week. It is

rumored that he is backed by London capital and is looking toward the Keystone mine.

Madera.

GAUS GULCH MINES.—*Mercury*: Charles M. Ward, the mining expert and superintendent of the Mammoth mine at Grub Gulch, stated that mining matters in the Gulch are booming. The Mammoth mine is working with a full complement of hands and getting out good paying ore. The shaft is now down 300 feet and there are 1400 feet of drifts. The ore runs from \$6 to \$6000 per ton. The mine is lighted and worked by electricity.

The Starlit mine, which was sold by Mr. Ward to San Francisco capitalists, is being developed rapidly. It is down 320 feet already and a great body of rich ore is in sight. It is the intention of the owners to fully develop the mine before beginning milling operations.

The Spencer mine is a good paying property and is being worked by the latest improved machinery. A ten-stamp mill is being run with profit to its owner.

Mariposa.

ON THE VERGE OF A BOOM.—*Gazette*: Hornitos appears to be on the verge of a mining boom. One day last week just after a heavy rain, a prospector went out to search for gold in the old placer dirt near the village, and before night he had cleaned up \$160, in ground that had been worked over many times. This was fair pay for one day's work, and shows conclusively that the mines are by no means exhausted. During the same week three men were prospecting near Muller's, six miles from Hornitos, when they came across a find of gold which gave them \$250. They found some gold in dirt which had been thrown out of a hole dug by a squirrel, and digging down found the nuggets, some of which weighed \$2.50. Mr. Muller thinks the gold had been buried there by some one long ago. This may be the correct theory, but all the country around Hornitos has always been gold producing. Less than three years ago the writer saw a piece of obsidian, as large as a man's head, picked up in that immediate vicinity, which was thickly veined with gold and which yielded almost an ounce of the precious metal. It will pay to examine squirrel holes and bits of obsidian down there.

Tuolumne.

GENERAL MINING NOTES.—*Independent*: The Laura and North Star mines located on the Enreka vein at Cherokee. The shaft is down 400 feet. The drift to the south intersects a three-foot vein, and shows well in sulphurets of high grade.

The Rawhide mine is now running steadily. The water is subdued and the mill is pounding away on their usual rich ore.

The Rappahannock mine, north, adjoining the Rawhide, is in operation. A shaft is being sunk about 500 feet from the south boundary, with the view of determining the value of the lode in that portion of the property. The old south shaft, now under water, contains a rich shoot of ore, which will be reopened in the near future, when the owners determine what power they will adopt—water or steam.

Col. Jack Coles is operating the Worcester mine, which is situated to the south of Summerville, and is a parallel vein to Eureka. The vein is four feet wide and shows gold freely in the rock, which also carries high-grade sulphurets of heavy percentage. The colonel has of late been pumping the water out of the shaft, which being now successfully accomplished with the aid of steam power, has commenced to drift north and south to develop his property.

The Seminole mill has just been completed with ten stamps, and is running. The vein is fully four feet wide, free gold being seen in the rock daily. There are over 500 tons of ore on the dump, ready for crushing. The ore shoot is found to be 200 feet long. Twelve men are employed in the mine. The power used is water from the Dead Horse ditch.

The Red Haw is a newly-discovered mine, situated between the Young America and New Albany. It is a parallel vein to the Seminole, from one to four feet. So far, fifty feet of shoot is opened up. Rock will pay \$10 per ton.

ARIZONA.

GENERAL NOTES.—*Journal Miner*: There seems to be a general move being made to Hassayampa section among miners. Another instance where history is repeating itself.

Several dry-washing miners are working in Rudy gulch, near Copper Basin, and are making good wages from the gravel there. From six wheelbarrows of dirt two men recently obtained \$5.50 in the yellow metal, so a report says recently.

The Gladiator mill is running on half time, owing to a scarcity of water. The company is endeavoring to secure a permanent supply in a near locality, and thus permit of steady running. The mine is looking better than ever.

A steam shovel is now being talked of for use in the Black Canyon gold fields. San Francisco and New York capitalists are behind the enterprise, and are now energetically pushing the matter to an active state in practical mining. Mr. W. D. Church, one of the original promoters of the scheme, and who will act as the general manager of the company, will leave tomorrow, in company with two experts, representing respectively the Eastern and Western stockholders, for the scene of future operations.

The Valencia mine in Black Canyon district, about four miles from Bumblebee station, was bonded last evening by Messrs. Dodson & McPhee to Denver parties, the consideration being \$12,500 in cash with other agreements. Improvements are to be placed upon the property. A five-stamp mill is at present located upon the mine, while five additional stamps are en route. The mine is an old one and has a shaft 90 feet deep with a 36-inch vein of free gold ore at the bottom. The new operators of the mine

intend to thoroughly work their recent purchase and feel confident of making a success of it.

Encouraging news has been received concerning the mines in the Francis district, 45 miles north of this city, during the week just past. Mr. P. Johnson returned from Rain Tank with the information that the two men sent out by a company of Williams citizens have discovered a well-defined ledge which promises to eclipse anything yet uncovered. Samples of the ore are now en route to the Selby Smelting Company, San Francisco, and it is expected that when the returns are received, a general stampede will occur.

Mark Bradley made a very rich strike of gold sulphuret ore on Slate creek last week. The ground has never been located heretofore. The ledge is two feet wide and the ore goes \$250 per ton in gold. It is fine concentrating ore, and gives good promise of developing into a good claim.

In a short time the famous Vulture mine may once more resume its ancient activity. Hon. Thomas Farish's lease on it expired yesterday. He has made money by running only ten of the eighty stamps and using the water in the mine. This morning, W. L. Cooper, one of Senator Tabor's trusted mining lieutenants, leaves for the property, and will await his chief and the latter's brother-in-law, Peter McCourt. The chief improvement needed is ten or twelve miles of water piping from the Hassayampa, which was carried away by the great Walnut Grove flood.

Mr. Burns, who recently discovered in Peoples canyon what was supposed by many to be the Nigger Ben mine, is giving his new bonanza a thorough prospecting, and is being rewarded handsomely for his good luck in the discovery of the property. The ledge prospects well for 30 feet across, being a deposit, while a one-foot streak was run into a few days ago which goes so high that the owner is sacking the ore from it for shipment to Prescott as soon as means of transportation can be afforded.

ALASKA.

Juneau News. F. D. Nowell, general manager of the Berners Bay Mining & Milling Co., brought down with him from the Comet mine yesterday a small sack of ore, taken from a four-foot ledge in tunnel No. 2. It is some of the richest free-milling gold quartz ever brought here from the mine, and its richness and fine appearance is the talk of the miners about town. It is white quartz, mineral stained, with free gold shining from the surface and permeating its texture. The management is highly elated over the splendid showing in the mine. On Tuesday the men in the crosscut holed and made connections with the winze from the upper workings, striking the winze almost squarely. An ore chute and manway will be put in the winze, and all the ore will pass through from tunnel No. 2 into the crosscut, and thence out to the surface and station of the tramway. The crosscut is 700 feet long, and for several weeks a hand blower had to be run to furnish air to the gang of men, as it became stagnant and bad. The mill is ready to drop stamps on ore from the bin, and all that is wanted to unhang the stamps and let them drop is water.

BRITISH COLUMBIA.

BACK FROM BIO BEND.—*Nelson Tribune*: William Hennessy and M. H. Hubbard returned from a trip to the Big Bend country on Tuesday. They report it useless for prospectors to go into that section earlier than July 1st, as the snow is yet very deep in the mountains. The Consolation claim on French creek is paying well. The pay gravel is not more than six inches, but the bedrock is worked to a depth of 2½ feet, it being coarse slate. The face is about 30 feet in width, and the dirt is run some 600 feet and hoisted 50 feet to the surface. It will, however, soon be hoisted through another shaft nearer the face, and a considerable saving will be made in labor. The dirt pays about \$30 to the yard, and the dust is worth \$18.75 an ounce in San Francisco. Several claims will be worked on McCulloch creek. Mr. Hennessy and Thomas Lidster have both become interested in claims on that creek. A party is at work on ground four miles from the mouth of Carnes creek, and reported taking out good pay. The quartz ledges in the Big Bend are from 15 to 20 inches wide, and it is claimed the ore runs from \$30 to \$50 in gold to the ton. John Boyd has bonded a claim located about 10 miles up Carnes creek, and is now cutting a trail to it. The vein is said to be nine feet wide, and in slate, granite and porphyry. The ore runs from \$10 to \$40 in gold.

MANITOBA.

A BIO STORY.—An immense body of auriferous ore a mile wide by two long is reported to have been discovered between Rat Portage and Fort Arthur, 70 miles south of the Canadian Pacific railway. Assays average \$3 in gold and \$4 in silver. Geologists have expressed the opinion that the deposits may be from 8000 to 10,000 feet deep.

MONTANA.

THE ELKHORN.—The Elkhorn mine has sunk another lift to the 1600-foot level and crosscut 800 feet south, striking a very rich body of ore. Parties who have seen it declare that it is larger than any ever encountered in the Elkhorn. It is of a free-milling character, with very little base. The company has now an ore reserve sufficient to last three years without further development. Between 135 and 140 men are on the payroll. There is a 30-stamp mill, in which most of the ore is worked. The base, which amounts to about a carload a week, is sent to the East Helena smelter for reduction. The ore reserves run all the way from the bottom to the top. The poorer quality of the ore is not taken out and will remain until there is an upward movement in the price of silver. The fire escapes in the mine are poor and there

is no fire department. The ventilation of the underground workings is perfect. No square sets are used and stulls are procured from the surrounding hills with which to do the timbering. The old stopes are filled in with waste from the ores, which are carefully sorted before being hoisted. Miners receive \$3.50 per day and muckers \$3. All the topmen, with the exception of the mechanics and those employed on expert work, receive the same rate.

CATAACT DISTRICT.—*Basin Times*: The Eva May mine.—The shaft is a two-compartment one and is 350 feet in depth. There are three levels, at the 100, 200 and 300, respectively. The 100 connects with a drain tunnel run in on the lead from the bed of the creek, entirely on ore, and this portion of the mine has been extensively developed, as there is a large quantity of ore at the month of the tunnel that came from these workings. On the 200 there is a small station which crosses the lead. On this level the face is in 30 feet of first-class ore and there is a winze 75 feet deep 50 feet from the station in ore which will assay not less than \$100 per ton. At the bottom of the winze drifts have been extended east and west in fine bodies of ore, and half a dozen candles must be kept burning to make any light at all, owing to the black ore that prevails on every hand. On the 350 drifting continues east and west. On this level the lead is 90 feet wide, with 30 feet of fine concentrating ore. The lead is cross-cut to the hanging wall and in no place is it less than 90 feet wide. The character of the ore in this lead is the same as in all the Cataract country; while there are some extraordinarily rich bunches, the average of the lead is also very rich.

UPPER BASIN CREEK.—S. H. Haggerty, from Upper Basin creek, reports that the snow is all gone. On the 21st of April it was four feet deep on a level. The snow that remains in the mountains is melting so rapidly that it is feared the placer miners will not have as long a season as was expected.

The Winters Brothers and Brown and one man are working with a monitor on a six-foot bank of gravel that goes 25 cents to the pan. They expect to take out not less than \$10,000 this season.

The Robert Burns attempted to sink three winzes this week, but the water came in so fast that work had to be stopped. The ore is very fine, containing gold, silver and copper. A quantity was shipped from the tunnel level and paid handsomely. This property is 10 miles up Basin creek in an undeveloped country.

NORTH CAROLINA.

ONLY A LITTLE GOLD.—*Butte Miner*: George W. O'Dell returned a short time ago from Monroe, N. C., the reputed gold fields about which the newspapers of the South have had so much to say lately. He represented a Butte company which contemplated the purchase of a big body of placer ground in case it proved as good as reported. He found gold, but the metal was too fine and not in paying quantities; and even if there had been gold in abundance there was not sufficient fall to mine it without entailing an enormous expense, as water would have to be flumed a great distance. Two young men had taken up most of the ground and were working negroes at 50 cents per day, but even at that low rate were obliged to suspend operations on account of the meagre returns. The men have had an idea that they had discovered another Alder gulch, and anticipated accumulating immense fortunes. Mr. O'Dell also visited the quartz mines of Charlotte, N. C., upon which operations were suspended nearly 70 years ago, and of which he formed a very favorable opinion.

SOUTH DAKOTA.

MORE CYANIDE WORKS.—*Deadwood Pioneer*: A brick weighing \$6300 came up from the Cyanide works yesterday. This represents a two weeks' run and the saving of the assay value of the ore of 90½ per cent. Doctor Taylor, who has just returned from St. Louis, says that the cyanide plants at Deadwood and Pluma are not the only ones that will soon be running in the Hills; that he had parties coming here from St. Louis who would be in the country by the 1st of July, and who were prepared to back up the building of cyanide plants. The returns from the ore of the Big Bonanza mine make it more than ever apparent that the cyanide process as a gold-saver is in the ascendant, and that it is the coming mill will be proved as time goes on. Doctor Taylor is enthusiastic, and he has the past test runs of the Deadwood works to bear him out in all that he claims, viz., cheapness and saving a higher percentage of the assay value than any other process here in the Hills.

UTAH.

FROM POVERTY TO WEALTH.—*Salina Press*: A large body of ore was opened up in the Carrie mine, on the Baldy mountain, last Saturday, and a streak in the center of the vein about a foot wide, which will run from \$500 to \$800 per ton in gold and silver—mostly gold—was discovered. It is estimated that \$1000 worth of ore was knocked in one shot that day. The mine is owned largely by the Butler Bros. of this city, who have been working and half starving themselves the past two or three years to open up the property. They first run in a tunnel, which crossed the vein near the top, and last winter they started another tunnel about 60 feet lower down; with this they tapped the vein with the above result. They had been running along in talc for about ten feet beside the vein without knowing it. The present opening shows a large body of rich ore, besides much of a lower grade. This strike promises to make the Butlers the wealthiest people in this part of the country, and they can be congratulated on their energy and pluck. The Butlers are awful good people now, but it has been a grave

question when they were going to get the next sack of flour last winter.

WASHINGTON.

A CHEERFUL VIEW.—Loomiston Journal: The Similkameen river has been on a tremendous rampage for ten days past, and has marked the highest in years. Considerable damage has been done by the raging waters, but there is one feature not to be overlooked, and that is that the immense flood has torn up to a great extent all the old bars and washed up great quantities of placer gold from the bed of the stream and placed it where the ever-ready miner will be able to get and redeem it from its resting places of ages. Ten thousand men working a year could not have so turned over and rearranged this sand and gravel of the Similkameen, and the knowing ones who are here are already outfitting and getting ready to go to work as soon as the waters subside. Another thing in favor of the placer miner is that the bulk of snow tributary to this river will have gone off during the recent warm spell and the river will fall much lower when it does fall than for many years past. Taken altogether, there has nothing happened for years in this placer mining business of as much benefit as this recent high water in the Similkameen.

Coast Industrial Notes.

—The Risdon Iron Works are building a plant for the Gwin mine, in Amador.

—The Skagit Boom and Lumber Company of Tacoma has incorporated, with a capital stock of \$25,000.

—The Northwestern Milling and Power Company of Spokane has incorporated, with a capital stock of \$750,000, to construct and operate mills of all kinds.

—The Cass-Camp Pile Preserving Company has incorporated, with a capital stock of \$100,000, to deal in patent rights for preserving piles and to take contracts for preserving piles and timber.

—W. E. Baines, of Marshfield, Or., intends to construct a log raft and tow it here. Captain Robertson, who contrived the Leary cigar-shaped raft on the Atlantic coast, is interested in the enterprise.

—The opening of the Mendocino county coal fields means much for the manufacturing industries of the coast, if, as it is claimed, the coal can be mined for \$1 a ton and laid down here for another dollar.

—From January 1 to June 1, '94, the shipments of shingles and lumber from Seattle, Wash., via the Northern Pacific railway were 2681 and 67 car loads respectively. For the first five months of '93 they were 2836 and 396.

—The \$20,365.38, the unexpended money of the California appropriation for her exhibit at the World's Columbian Exposition, has been paid over to the State Treasurer by Irving M. Scott, president of the California World's Fair commission.

—Hallibut weighing 30 and 40 pounds were sold at the Tacoma water front last week for 25 cents each. The fish belonged to the North Pacific Fish Company. On account of the floods they could not be shipped east, as is usual, and it was a case of selling them at what they would bring or letting them spoil.

—The Oriental Gas Engine Works, 105 Beale street, this city, has just completed a marine engine of 30-horse power, new design. It will be placed in a new freight boat belonging to Lynde & Hough for service on the bay. These works are also turning out a new pattern of horizontal gas engine for general purposes.

—A syndicate of San Franciscans are arranging to systematically work a big placer bank on Salmon river, a tributary of the Yukon. They will purchase a steamer on Puget Sound to carry the mining machinery to the placer bank, which is reported to be over a mile long and is said to contain several million dollar's worth of gold.

—E. G. Denniston, proprietor San Francisco Plating Works, 653 and 655 Mission street, has a large exhibit of silver-plated copper mining plates in quartz and placer mining at the fair that has attracted considerable attention. They contain over 400 square feet of surface, and are believed to be the largest ever made. He has five exhibits, four in the Mechanic Arts building and one in the quartz mill building. He has presented the State Mining Association with \$100 in coin and a \$150 silver-plated copper mining plate for saving gold.

Hernia.

Attention is directed to the advertisement of Dr. J. C. Anthony in another column. Though a graduated physician, Dr. Anthony makes the treatment of rupture a specialty. His method is scientific, and the great success with which he has treated some of the most difficult cases, effecting complete cures, has given him a high, wide-spread and well-deserved reputation. Those who are afflicted will do well to call upon or correspond with him, at Room 87, Chronicle Building, this city.

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market St., S. F.

FOR THE WEEK ENDING JUNE 12, 1894.

521,228.—MUSICAL INSTRUMENT.—C. L. G. Bech, Bellevue, Wash.
521,201.—LAMP STOVE.—F. E. Browne, Los Angeles, Cal.
521,260.—ELECTRICAL BATTERY.—Duhero & Mohrdeck, S. F.
521,262.—CAR COUPLING.—J. D. Gooley, Portland, Gr.
521,414.—BEVEL.—J. L. Langlate, Berkeley, Cal.
512,378.—ANIMAL TRAP.—Loomis & Hartle, Watsonville, Cal.
521,233.—DETACHING BLOCK.—G. W. Moore, Gardner, Gr.
521,272.—CULTIVATOR.—J. Schumann, Anaheim, Cal.
521,297.—PLANNER FEED ROLL.—J. D. Sigler, S. F.
521,422.—TELEPHONE CALL RECORDER.—W. F. Smith, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SOLICITORS PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CURB AND PAVEMENT.—No. 520,220. May 22, 1894. Patrick W. Reardon, Oakland, Cal. The object of this invention is to provide a suitable curb or wall for pavements, whether sidewalks or streets, of that class in which various forms of asphaltum or bitumen are used. This curb consists of an exterior body with an interior core, the body being made of asphaltum composition of suitable character, and the core may be made of some hard material like wood or metal. It may be made in several pieces, with suitable means for connecting these together. The core pieces are placed in the mold, and the exterior body is formed around them so as to unite the whole in a solid single body. The curb thus made resembles the body of the walk or pavement and the core gives it sufficient strength to retain its shape and resist injury.

SULKY PLOW AXLE.—William B. Morris, Collinsville, Cal., assignor to E. I. Upham and William Emington. No. 520,934. Dated June 5, 1894. This invention relates to improvements in axles for sulky plows. It consists of a short independent axle pivoted to the main axle, and a means for tilting it about its pivot point so as to change the axle in a vertical plane, and thereby incline the wheel to any desired degree from a perpendicular so that the tendency to move away from the line when plows are used upon a side hill will be counteracted, and the plow will be held to the land and caused to run approximately upon the same level. The pivoting and locking mechanism enables the operator to adjust this axle and its wheel to any desired angle to suit the slope of the land upon which the work is being done.

DETACHING PULLEY BLOCK.—No. 521,293. June 12, 1894. Gladius W. Moore, Gardner, Oregon. This invention relates to detaching or latch blocks in which the keeper is hinged to the stock, and is held in place by a swinging link. The object of the invention is to provide such a block with an accurate slide fitting and applicable to any use requiring the detaching of a rope or chain from any fastening to which it may be secured, as, for example, in hauling or logging operations, in which its employment obviates the necessity of slacking or backing the team as is necessary to unhook common chains from their fastenings. It consists of a stock having separated ears at one extremity, a terminal bearing at the other end, and an intervening uprising tongue on the inner edge, the keeper having the tenon fitted and pivoted between the ears of the stock and resting, when closed, upon the tongue and terminal bearing of said stock, thus forming a bed for the detaching link, and a locking clevis to hold the keeper to the stock. Upon the binged pintle of the stock and keeper are axially turnable disks having the peripheries exposed to the link bed, so that the link is directed clear of the binged and block as the keeper is thrown back.

ELECTRIC BATTERY.—Fred Dubero and Peter Mohrdeck, San Francisco. No. 521,260. Dated June 12, 1894. The object of this invention is to provide a continuous or constant battery, the elements of which are recharged during the operation of the battery, and in the employment in conjunction with said battery of sea water as an active energizing element. It consists of containing tank, an interior positive element suspended within the tank having a connection for the positive wire, a negative element consisting of a revoluble hollow cylinder with a filling of negative material, and perforations through which the exciting fluid may reach the material when submerged and be drained from it when raised out of the liquid by the rotation of the negative element, and in conjunction therewith of a means for supplying sea water, which is introduced near the bottom of the containing tank and discharged at a point near the top.

MUD AND OIL TRAP AND WATER PURIFIER.—George F. Day and William Hunter, S. F. No. 520,670. Dated May 29, 1894. The object of this invention is to provide an apparatus for heating and purifying water; for withdrawing the mud or sediment which is deposited in the water, and in conjunction therewith providing an oil trap and means for withdrawing the oil which constantly accumulates from the engine and which, if allowed to pass into the boiler, produces foaming and other objectionable action. The apparatus consists of a vertically disposed chamber having transverse partitions dividing it into compartments. Water is received into the upper compartment, and flowing over shelves which distribute it into thin sheets, it is exposed to the action of exhaust steam which passes through the chamber and heats the water to such a point that lime and similar impurities will be deposited by the well-known action of heat upon water containing them. The water then flows from this chamber to a chamber at the bottom through a connecting pipe, which chamber is conical in shape

and allows the mud and sediment to settle to the bottom, where it can be drawn off from time to time by a cock and pipe opening out from the bottom of the cone. This conical form also serves, when the cock is opened, to draw down, as in a funnel, any oil or light material which may collect upon the surface of this water. Above this chamber are one or more chambers containing any material which serves to arrest such sedimentary deposit as may still remain in the water, the water flowing up through the perforated partitions which separate these chambers from the lower one and from each other. Above these chambers and below the first chamber into which the water is received, is an intermediate chamber for the purified water, from which it is drawn from time to time as needed in the boiler or for other purpose.

PLANNER FEED ROLLS.—John D. Sigler, San Francisco. No. 521,297. Dated June 12, 1894. The object of this invention is to provide a rigid sectional feed roll, the different sections of which will adapt themselves to strips of varying thickness which may be passed through the planer, and which, by reason of having their lower surfaces resting upon the bed of the planer, will have the upper surfaces of irregular heights. The rolls will adjust themselves automatically to the irregular thickness of the strips to be planed, and at the same time are held in position to engage the driving gears. It consists of the independent rigid cylindrical sections provided with internal bores, cylindrical sleeves within said bores having approximately the same length as the sections, having their lower ends open, and a shaft fitting into the channels in the lower part of said sleeves which allows them and the sections to rise and fall independently. There is a connection between the shaft and each section to guide the vertical movement of the section and prevent its moving endwise.

METALLIC PISTON ROD PACKING AND GLAND.—Charles H. Eosigo, Kekaha, Kauai, H. I. No. 520,954. Dated June 5, 1894. The object of this invention is to provide a metallic packing for reciprocating piston and other rods in which the packing rings are fitted into and enclosed within the removable gland of the stuffing-box, with means for adjustment. The gland has inner and outer chambers and an intermediate annular flange, the gland nut fitting within the outer chamber, and the packing rings, which are less than the diameter of the inner chamber, are seated therein so that a surrounding steam space is formed. One of the rings has its end projecting and an elastic ring surrounds the packing rings, holding them in place when not under steam pressure. The outer end of the inner chamber is closed by a cap bearing against the extension of the ring so that the two ends of the rings are held to form a steam-tight joint.

RUPTURE.

It has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But Dr. J. C. Anthony of 86 & 87 Chronicle Building, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats and does not ask a man for a dollar unless he cures him so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

HEALD'S

BUSINESS COLLEGE.

24 POST STREET.....SAN FRANCISCO.

FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing, Book-keeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils. Our school has its graduates in every part of the State. SEND FOR CIRCULAR. E. P. HEALD, Pres., O. S. HALEY, Sec.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

SEND FOR PRICE LIST.

Adamantine Shoes and Dies

—AND—

CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

Stamp Cam.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for packing on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-lightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.

WM. NANGE, Grass Valley, Nevada County, California.

Market Reports.

The Markets.

SAN FRANCISCO, June 21, 1894.

The advance and recession in the price of silver during the week left it at practically the prices of seven days ago. In copper a sale is reported of 20,000,000 pounds by the Calumet & Hecla at nine cents for delivery by Nov. 1st. The reduction in the duty in quicksilver from ten to seven cents a pound is interpreted to mean a reduction of three cents a pound, or \$2.30 a flask. Regarding the rescuing of quicksilver from the free list, the *Call* of this city, in the current issue, says:

The quicksilver miners of California leaned back in their chairs with a sigh of relief and mopped the sweat of long-standing anxiety from their brows when they read the dispatches from Washington yesterday morning. Senator Perkins had saved the tariff on quicksilver. One of the State's most distinctive and richest industries was no longer in danger of being sunk in the bottomless sink of mis-legislation.

The story was that as the tariff bill left the House quicksilver was removed from the list of dutiable minerals. In the McKinley bill it bore a tariff of 10 cents a pound. The California miners, who are the only producers in the United States, at once set to work with figures and influences of various sorts to prevail upon the Senate to amend the matter. Things had been in a stew of unrest ever since until yesterday.

Mr. Staacke of the Bell Mining Co., when asked how the adjustment would satisfy the parties concerned, said: "Well, it's a compromise. Better half a loaf than no bread at all. The quicksilver mines have not been making any money for some time past, even under the McKinley law."

"Had the duty been removed entirely, we should simply have had to drop out of existence. It would be impossible to compete with the Rothschild Almaden mines in Spain, where the cost of labor is virtually nothing, and where the ore is extraordinarily rich and inexhaustible. What there costs only \$1 to produce costs \$10 here. Besides the output of the California mines more than supplies the demand of the American market when at its highest point."

"Since the price of silver went down and the mines all over the country closed up, the quicksilver trade has amounted to nothing. Silver mines consume one hundred times as much quicksilver as the gold mines. A hundred-stamp mill reducing silver requires as much quicksilver as all the gold mines in California. To show how little the latter use, the great Kennedy mine, which is paying \$40,000 to \$50,000 per month in dividends, does not require more than about one flask (76 1/2 pounds) per month."

"The total production of quicksilver in California under normal conditions is about 30,000 flasks a year. The old Almaden mine in Spain is producing at present some 50,000 flasks. Other mines in Europe are putting out about 20,000 flasks, making the total output for the world about 100,000 flasks. The American market now consumes no more than 15,000 flasks, if that many, which is one-half the possible supply of this State. So we are compelled to enter the European and Mexican markets in competition with Rothschild's great Almaden resources. Therefore it is easy to see how reasonable has been our anxiety about the preservation of the duty on our minerals. The figure should really have been maintained at 10 cents; but, as I said, we are glad to accept 7 cents when we can get no more."

Other prominent miners all accorded with Mr. Staacke. Without the tariff their business would have been ruined. With the prospect of losing it, one firm at least had prepared to close its mines.

The credit for the good work in Washington was generally conceded to J. B. Randol, of this city, whose name was quoted in the dispatches as having furnished important information to the Senate through Senator Perkins. Mr. Randol is recognized as an authority upon quicksilver mining.

A coal circular says: During the week 28,224 tons have arrived from the coast mines. Business generally is very quiet, as consumption is gradually easing off, the demand for domestic uses being very much lighter. The market is completely bare again of Australian; the last cargo which arrived has been already distributed among consumers, and some overdue vessels are anxiously looked for. In the interior British Columbia shipments are finding ready sale at full figures, and on arrival each vessel's cargo is delivered with dispatch.

Mining Share Market.

SAN FRANCISCO, June 21, 1894.

Little life was manifested in transfers during the week, nearly every one catching at the outcome in the 1700 level of the Con. Cal. & Va. as something to wait for. Next week's holiday will close a dull month in stocks. What July will bring is problematical. The total sales for last week were \$13,456. *The Enterprise* says:

Little can be learned of the result of the drilling on the 1700 level. The hole made through the recently discovered ore body on Sunday only shows the width. The ore extends both downward and toward the north, in which direction the drift is being run. Nothing of the width of the body at any other point is known, and it is presumable from the indications above that the ore was cut through at a narrow place. It is sincerely hoped that this is the case. An upraise for ventilation is being sent up from the west crosscut near the ore, which is an indication that more men will be put to work.

The Morgan mill will start in a few days to crush the large accumulation of high-grade ore from the Con. Cal. & Va. mine.

The supply will be kept up for a long time from the new ore body and from other points in the mine.

In the Occidental from the west ledge above the 400 level they continue to extract about eight tons of ore per week, of the average value of \$41 per ton as per car sample. The crosscut started near upraise 3 on the 500 level is in seven feet; face in hard porphyry.

In the Kentuck they have stopped work on the 1035 level for the present and have started to sink a winze in the east ledge on the 1100 level. The south drift from the Jacket incline is in 114 feet and continues in low-grade gold ore.

At the annual meeting of the stockholders of the Bodie Mining Company, 82,690 shares were represented. The following officers were elected for the ensuing year: H. D. Walker, president; R. B. Woodward, vice-president; E. P. Danforth, J. W. Kelley, M. E. Willis, W. H. King and L. Osborn, directors. M. E. Willis was elected secretary; J. W. Kelley, superintendent. The secretary's financial statement showed a credit of \$11,376.33. A motion to declare a stock dividend on the 11,030 shares of stock remaining in the company's treasury failed to carry. The president was subsequently authorized to sell the stock for the benefit of the company.

In the Savage on the 1030 level the west crosscut from the top of the upraise in the north drift has advanced 14 feet, total length 43 feet; face is in quartz giving some fair assays. The north lateral drift from the station was extended 11 feet, total length 106 feet; face is in ledge formation. They have started a west crosscut from the sixth floor of the south ore slopes and advanced same 12 feet; face is in quartz giving low assays. On the 1100 level west crosscut 2, started from the face of the north drift, was advanced 29 feet when it reached the west boundary of the quartz body and was discontinued; total length of drift, 106 feet. Work was resumed on the face of the north lateral drift on this level. During the week they have hoisted 77 cars of ore. Car samples average \$25.23 per ton.

The following illustrates the changes of the week:

DIVIDEND NOTICE.

SAN FRANCISCO SAVINGS UNION,
533 California St., Cor. of Webb.

For the half year ending with the 30th of June, 1894, a dividend has been declared at the rate of four and eight-tenths (4 8/10) per cent per annum on term deposits and four (4) per cent on ordinary deposits, free of taxes, payable on and after Monday, the 2nd day of July, 1894.
LOVELL WHITE, Cashier.

Assessment Notices.

OCCIDENTAL CON. MINING COMPANY—LOCATION of principal place of business, San Francisco, California; location of works, Silver Star Mining District, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Trustees, held on the thirty-first day of May, 1894, an assessment (No. 16) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the fifth day of July, 1894, will be delinquent, and advertised for sale at public auction, and unless the payment is made before, will be sold on TUESDAY, the thirty-first day of July, 1894, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Trustees.
ALFRED K. DUREBROW, Secretary.

Office—Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from L. V. Teft in the Oconordia mine, near Oronburg, Plumas County, to deposit tailings behind dams in Cogswell Ravine and Jackson Creek; from the Northern Placer Mining Company in their mine near Oronburg, Plumas County, to deposit tailings behind brush dams in Little Long Valley Creek; and from Thomas White in the Schuyler mine, near Dry Creek, Shasta County, to deposit tailings behind dams in Dry Creek, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on June 26th, 1894, at 1:30 P. M.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS Was awarded the Highest (Bronze Medal) 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$575 f.o.b. Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven,

are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

THE SAN JACINTO ESTATE—Office of the General Manager, OAJALCO, Oct. 30, 1891.

GEO. E. WOODBURY, Esq.—Dear Sir: In reply to yours of the 27th inst., respecting the working and efficiency of the "Woodbury" Concentrator placed in our works by you, I am pleased to inform you that it is giving entire satisfaction; it has a much greater capacity than any other machine, and is doing fully one-third more work, with the concentrates equally clean, as from either of the machines at work here. Yours faithfully, S. HARRIS, Manager.

PATENTED Aug. 13, 1890.

GEO. E. WOODBURY, Manufacturer, 213 to 219 First Street, San Francisco, Cal.

Air Compressors and Pelton Wheels.

Herewith is shown a pair of Ingersoll-Sergeant compressors driven by Pelton wheels attached to driving shafts direct. This plant was built for a mine in Peru, South America, located in the heart of the Andes, some 100 miles east of Lima, and was made in sections for mule packing, no piece in the entire outfit exceeding 300 pounds in weight.

The wheels are four feet diameter and run under a head

twelve or sixteen feet in diameter, as may be necessary to give proper speed to the machinery they are designed to run, suiting the buckets and nozzle delivery to conditions as to head and power requirement.

Fly-wheels were made necessary in the case here referred to from the fact that the water head was too low to admit of making the wheels large enough to carry the weight required for combined motor and fly-wheel and give the necessary speed to compressors.

Full information regarding such an application as is

An Important Project.

Capt. De Lamar, famous in Idaho, has a scheme, said to be well backed financially, which is of great interest to a rich mining region comprising western Utah, southern Nevada and southwestern California. He has lately bought the principal mines in the once-famous Ely district, comprising Pioche, Nev., and outlying territory, and considerable valuable water rights and railroad property, and is about to build a railroad from Milford, the present

PAIR OF INGERSOLL-SERGEANT COMPRESSORS, WITH PELTON WHEELS.

of fifty feet, making 120 revolutions. Water is brought from a stream through a line of 18-inch pipe, and applied to the wheels by double nozzles with three-inch openings. The air cylinders are ten inches diameter by 18-inch stroke, and the wheels under this comparatively low head afford sufficient power to maintain seventy pounds pressure on the receiver at an elevation of 10,000 feet above sea level.

The advantages of attaching the wheels to the compressor shafts are: Economy of power as well as in first cost; lessened cost of freight, and lessened cost of setting up the machinery, as well as in the absence of belt connections, the maintenance of which with loss of power involved are matters of importance in many mining localities. This application of the Pelton wheel is made with equal facility to all forms of compressors, as well as blowers and many other classes of machinery, and where the head admits, the wheel can be made heavy enough to serve as a fly-wheel, thus simplifying and cheapening still more this manner of applying power. Wheels in such cases may be made of any size ranging from six up to

here shown can be obtained from the Pelton Water Wheel Company of this city, or from their New York office, 143 Liberty street.

THE "State Anti-Debris Association" has addressed a long letter to the United States Debris Commission, in which the Association proffers, "without cost," the services of its paid spies. This is a bold bid for alliance. The "Association" does not seem to realize that dignity demands that a Federal organization should be unapproached by such offers from any source. Such action can only serve to cover the Association with deserved contempt.

SOME good men in Chicago are advertising an Idaho mine that "will pay a net profit of \$1000 a day." They are willing to let the stock go at prices reasonably dear, though it is evident that pure philanthropy prompts their motives, as it would be so easy to keep the stock of the mine at Gibbonsville, Idaho, themselves, and, incidentally, keep the daily profit of a thousand dollars therefrom.

terminus of that branch of the Union Pacific, to Pioche, and southwesterly, connecting with the Nevada Southern, now building eastward from Barstow, San Bernardino county, this State, on the Atlantic and Pacific. The length of the main line of the road from Milford to the Pioche property will be two hundred miles. This will be a boon and a boom to a rich but isolated mining region, and, incidentally, will result in an additional line of railroad from the Wahsatch to this State.

This paper is in receipt of arguments for and against the passage of an extension of time assessment law. The chief argument of those against it comes from the State of Washington, and practically is that it will prevent men from getting a job to do the work from the owner of the property, and that it will "prevent the development of the country." Assessment work, ordinarily, does not "develop the country" very much, and where one man is kept out of a job by the operation of the extension, a hundred will be relieved of a compulsory expense at the very time when relief will be of most benefit. The bill will go through all right and is a present necessity.

Four Centuries of Fluctuation.

It is by comparison of long periods of time that the most correct estimates can be made of the truth or falsity of certain statistical propositions. Upholders of the single gold standard claim that the violent fluctuations in the relative values of gold and silver in the last twenty years have been occasioned by the increased production of silver during that time. While twenty years is a long time in the history of a nation, yet twenty times twenty years is none too long in being taken as a period of time in which to illustrate similar fluctuations in so important and eternal a factor in the world's wealth as the relative values of gold and silver. Statistics of the annual production of gold and silver in the world since the discovery of America herein condensed to ordinary limits show that from 1492 to 1545 for each ounce of gold mined twenty-nine ounces of silver were mined. From 1545 to 1560 the proportion was 35 to 1; from 1561 to 1580, 45 to 1; from 1581 to 1600, nearly 60 to 1. From 1600 to 1840 the relative yield at no time fell below 22 to 1, and most of the time it ran from 25 to 1 to 50 to 1. In 1800 it was exactly 50 to 1. In 1810 the percentage was 1.9 of gold to 98.1 of silver. From 1841 to 1850, 14 times as much silver was mined as gold. Then came California and Australia, and till '60 the average was one ounce of gold to four of silver. Since then it is estimated the proportion has averaged 1 to 23.

When such a segment of time as that is taken it shows that unusual production of the yellow metal has been followed by excessive production of the white, and vice versa, and that in these great swings of the pendulum on Time's dial the relative proportion of the world's stock of the two has not been greatly disturbed.

There is nothing new about this question of monometallism or bimetalism. It is no more of a novelty than many other things of present discussion, supposed to be new, but in reality as old as the Book of Job. The only new factor is present environment, the change of rapid intercommunication, etc. The question comes up for the twentieth time, and will, doubtless, in the long run be settled as so often before, in favor of the only natural law—bimetalism—till the next upheaval comes, to be settled again the same way, and so on through the circling cycles of Time's changing course.

THE "Consolidated" mining cases at Mogollons, Socorro county, N. M., has been decided in favor of the defendants. It has attracted some attention among miners. It has been in the courts for over four years. The gist of the verdict is that so far as that case decides anything, where assessment work done upon one claim is to inure to the benefit of others, the claims must be contiguous, and all owned by the same parties, and the work must also tend to develop all the claims.

A Question for Decision.

A. Walrath vs. Champion Mining Co.

This cause, which was tried by U. S. Circuit Judge Hawley of Nevada, sitting for Judge McKenna in this city in the month of May, and which was submitted for decision, affects important property rights in Nevada county and involves legal questions which have not been heretofore decided as to the rights of the owners of mining claims held under patents granted under the act of 1866 as to veins other than the one upon which the patent was granted as well as to the construction of end lines.

In this action the plaintiff, A. Walrath, is the owner of the Providence mine; the defendant, Champion Mining Co., is the owner of the New Year's and New Year's Ex. claims.

In the year 1870 a patent was granted by the United States to the Providence lode, shown on the diagram at P. Q. R.; also to the piece of surface ground marked Providence. On this vein an incline shaft was sunk 1500 feet deep, and extensive mining operations carried on. From this shaft two crosscuts were run 600 feet to the west, and another vein opened up and worked by the Providence Mining Company, this hack vein having its apex on the line M. S. N.

On this vein, at the point S, the Champion Mining Co. has sunk a shaft 1000 feet deep on the pitch, and has extended its works and taken out ore south of the line E. B.

The plaintiff asks for an injunction to restrain defendant from working south of the line E. B., and for damages for ore removed south of said line.

The contentions of plaintiff are that whereas the act of 1866 only granted to the Providence claim the lode P. Q. R., that the mining act of Congress of May 10, 1872, gave it the additional grant of all other veins, the apexes of which were situated within the surface lines of said claim, with the right to follow the same on their dip to any depth, and that the line E. F., which is crossed by the apex of said vein, is the end line on said vein, and that the right to follow said vein on its dip and strike is limited by a plane passed through said line E. F. and its continuation.

It was further claimed that a location made by the Champion Mining Co. in the year 1884, containing a clause of abandonment south of the line E. F., made said line a compromise line, and that defendant was debarred from asserting any rights south of said line.

The defendant contends that the line E. F. is a line which limits the claim of the Providence mine to said vein on its strike, but that the rights on the dip are limited by a plane passed through the point A. and parallel with the line F. G., being the line crossed by the patented lode P. Q. R.

That the claimed abandonment was not of such a nature as to make the plaintiff a party to same, and that when defendant obtained from the land office the receiver's receipt for a patent, that it gave a new title, which barred any claimed compromise.

The portion of the mine in dispute is that portion of the hack vein included in the lines A. B. and A. C. The peculiarity of this action relates to the numerous irregular shaped pieces of surface ground which were patented to mine owners under the act of 1866 and the application of the act of 1872 and the decisions of the courts thereunder; the difference between the two acts being that under the law of 1866 a patent was granted for a number of feet of a vein, with a piece of ground for working purposes, which could be taken in any shape. Under the act of 1872 a piece of ground is patented, which is practically supposed to be a parallelogram containing a vein.

The decision is awaited with some interest.

Senate Bill No. 1515.

Following is the full text of Senator Stewart's bill, which passed the U. S. Senate on the 15th inst:

A Bill to Amend Chapter Six of Title Thirty-two of the Revised Statutes, Relating to Mineral Lands and Mining Resources.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section twenty-two hundred and twenty-four of the Revised Statutes be amended so as to read:

"SEC. 2324. The miners of each mining district may make regulations, not in conflict with the laws of the United States or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording the amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground by posts or monuments, so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of locators, the date of the location, and such a description of the claim or claims located as will identify the claim. On each lode claim located after the tenth day of May, eighteen hundred and seventy-two, and until payment of the purchase money and a certificate of entry has been issued therefor not less than one hundred dollars' worth of labor shall be performed or improvements made during each year. On all lode claims located prior to the tenth day of May, eighteen hundred and seventy-two, ten dollars' worth of labor shall be performed or improvements made during each year for each one hundred feet in length along the vein until payment of the purchase money and a certificate of entry has been issued therefor; and for each twenty acres of placer claims, and for each subdivision thereof less than twenty acres, fifty dollars' worth of labor shall be performed or improvements made during each year until payment of the purchase money and a certificate of entry shall be issued therefor. But where several adjoining lode claims, not exceeding five, are owned or held by the same person, association, or corporation, and the sum of five hundred dollars or more is expended in any one year in good faith for the development of all of the claims so owned or held, not exceeding

five, there shall be no requirement for separate labor or improvements to be performed or made on the several claims so owned or held during such year. The year within which the annual labor or improvements required to be performed or made by this section shall commence at twelve o'clock meridian on the first day of October of each year: *Provided*, That upon claims located previous to the first day of March to any year the annual labor or improvements shall be performed or made on such claims for that year prior to twelve o'clock meridian of the first day of October next succeeding; and upon claims located after the last day of February and prior to twelve o'clock meridian of the first day of October in any year the annual labor or improvements required shall be performed or made within one year from twelve o'clock meridian of the first day of the succeeding October: *And provided further*, That only one-half of the annual labor or improvements required by this Act shall be necessary to be performed or made prior to twelve o'clock meridian of the first day of October, in the year eighteen hundred and ninety-five, but after the first day of October, in the year eighteen hundred and ninety-five, the full amount of labor or improvements required by this Act shall be performed or made upon such claims as in all other cases during each year prior to twelve o'clock meridian of the first day of October. In case the first day of October falls on Sunday or any holiday the following secular day shall be construed as the first day of October within the meaning of this Act. When the labor required by this Act shall have been performed or the improvements made an affidavit may be filed within thirty days after the time limited for performing such labor or making such improvements with the recorder of deeds of the county in which the claim or mine is situated, particularly describing the labor performed and improvements made, and the value thereof, which affidavit shall be prima facie evidence of the facts therein stated. And upon a failure to comply with the conditions of this Act to the performance of labor or making of improvements, the claim or mine upon which such failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made: *Provided*, That the original locators, their heirs, assigns, or legal representatives, do not resume work upon the claim after such failure and before such relocation, and continue the same with reasonable diligence until the required amount of labor shall have been performed or improvements made; but no relocation of a claim by a person who has already located such claim and failed to comply with the conditions of this Act in performing work or making improvements shall be valid prior to such resumption and continuance of work upon such claim. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required hereby the co-owners who have performed the labor or made the improvement may, at the expiration of the year, give such delinquent co-owner personal notice in writing or notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days, and if at the expiration of ninety days after such notice in writing or by publication such delinquent shall fail or refuse to contribute his proportion of the expenditure required by this section, his interest in the claim shall become the property of his co-owners who have made the required expenditures. A copy of such notice, together with an affidavit showing personal service or publication, as the case may be, of such notice, when filed and recorded with the recorder of deeds of the county in which such mining claim is situated, shall be evidence of the acquisition of title of such co-owners. Where a person or company has or may run a tunnel for the purpose and with the intent to good faith of developing a lode or lodes owned by said person or company, the money so expended in running said tunnel shall be taken and considered as expended on such lode or lodes: *Provided*

further, That said lode claim or claims shall be distinctly marked on the surface, as provided in this Act."

SEC. 2. That section twenty-three hundred and twenty-five of the Revised Statutes be so amended as to read:

"SEC. 2325. A patent for any land claimed and located for valuable deposits may be obtained in the following manner: Any person, association, or corporation authorized to locate a claim under this chapter, having claimed and located a piece of land for such purposes, who has, or have, complied with the terms of this chapter, may file in the proper land office an application for a patent, under oath, showing such compliance, together with a plat and field notes of the claim or claims in common, made by or under the direction of the United States surveyor-general, showing accurately the boundaries of the claim or claims, which shall be distinctly marked by monuments on the ground, and shall post a copy of such plat, together with a notice of such application for a patent, in a conspicuous place on the land embraced in such plat previous to the filing of the application for a patent, and shall file an affidavit of at least one person that such plat and notice have been duly posted, and shall also file a copy of the notice in such land office, and shall thereupon be entitled to a patent for the land in the manner following: The register of the land office, upon the filing of such application, plat, field notes, notices, and affidavits, shall publish a notice that such application has been made, for a period of sixty days, in a newspaper to be by him designated as published nearest to such claim; and he shall also post such notice in his office for the same period. The claimant at the time of filing this application, or at any time thereafter within the sixty days of publication, shall file with the register a certificate of the United States surveyor-general that five hundred dollars' worth of labor has been expended or improvements made upon the claim by himself or grantors; that the plat is correct, with such further description by such reference to natural objects or permanent monuments as shall identify the claim, and furnish an accurate description, to be incorporated in the patent. At the expiration of the sixty days of publication the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during such period of publication. If no adverse claim shall have been filed with the register and receiver of the proper land office at the expiration of the sixty days' publication it shall be assumed that the applicant is entitled to a patent, and that no adverse claim exists, and upon the payment to the proper officer of five dollars per acre he shall receive a certificate of entry; and thereafter no objection from third parties to the issuance of a patent shall be heard except it be shown that the applicant has failed to comply with the terms of this chapter. But no more than three thousand feet in length along the vein on claims located prior to the tenth day of May, eighteen hundred and seventy-two, and not more than the extent of fifteen hundred feet in length by six hundred feet in width located after said date, shall be included in the same application for a patent, and not more than forty acres of placer or petroleum ground shall be included in the same application for a patent: *Provided*, That when fractional claims are located or sought to be patented between other existing claims the end lines may be made to conform to the lines of such adjoining claims."

SEC. 3. That section twenty-three hundred and thirty-four of the Revised Statutes be amended by adding thereto the following: "And the surveyors appointed under the provisions of this section shall have power to administer oaths to their assistants."

SEC. 4. That section twenty-three hundred and thirty-five of the Revised Statutes be amended so as to read:

"SEC. 2335. All affidavits required to be made under this chapter may be verified before any officer authorized to administer oaths in any State or Territory of the United States or in the District of Columbia having an official seal, and all testimony and proofs may be taken before any such officer, and when duly certified by the officer taking the same, attested by his seal of office, shall have the same force and effect as if taken before the register and receiver of the land office. In cases of contest as to the mineral or agricultural character of land the testimony and proofs may be taken, under such regulations and notice as the Commissioner of the General Land Office may prescribe: *Provided*, That the presence of rock in place bearing gold, silver, cinnabar, petroleum, or other valuable mineral shall be regarded as prima facie evidence that the land containing the same is mineral in character: *And provided further*, That in investigating the character of land with a view to ascertain whether it is more valuable for mineral than agriculture, evidence may be taken of the mineral discovered or developed adjacent to such land."

SEC. 5. That section twenty-three hundred and thirty-seven of the Revised Statutes be amended so as to read:

"SEC. 2337. Where non-mineral land not included in a lode claim is used or occupied, or is intended in good faith to be used or occupied by the proprietor of such vein or lode claim for mining or milling purposes, such non-mineral surface ground may be embraced and included in an application for a patent for such vein or lode claim, and the same may be patented therewith or separately, subject to the same preliminary requirements as to survey and notice as are applicable to vein or lode claims; but no location hereafter made of such non-mineral land shall exceed ten acres, and payment for the same must be made at the same rate as fixed by this chapter for the superficies of the lode claim. The owner of a quartz mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill site as provided in this section."

SEC. 6. Amend section twenty-three hundred and thirty-eight of the Revised Statutes so as to read:

"SEC. 2338. As a condition of sale each patent shall reserve the right of way through or over any mining claim for roads, ditches, canals, cuts, tunnels and other easements, for the purpose of working mines and for agricultural purposes: *Provided*, That any damages occasioned thereby shall be assessed and paid in the manner provided by the laws of the State or Territory in which such mine is situated for assessments and payments for land taken for public use under the right of eminent domain. And the rights and easements heretofore reserved under the provisions of this section (twenty-three hundred and thirty-eight of the Revised Statutes) in patents heretofore issued shall be regulated and made available as herein prescribed."

SEC. 7. That town-site entries may be made by incorporated towns and cities on the mineral lands of the United States, but no title shall be acquired by such towns or cities to any vein of gold, silver, cinnabar, copper or lead, or to any valid mining claim or possession held under existing law. When mineral veins are possessed within the limits of an incorporated town or city, and such possession is recognized by local authority or by the laws of the United States, the title to town lots shall be subject to such recognized possession and the necessary use thereof; and when entry has been made or patent issued for such town sites to such incorporated town or city, the possessor of such mineral vein may enter and receive patent for such mineral vein and surface ground recognized by the local laws and statutes of the United States not held or possessed adversely to the claimant for such mineral vein by other than the said city or town, or when it shall appear that the claimant otherwise entitled to such mineral vein has acquired title to such surface ground from the said city or town: *Provided*, That no entry shall be made by such mineral-vein claimant for surface ground where the owner or occupier of the surface ground shall have had possession of the same before the inception of the title of the mineral-vein applicant."

ELSEWHERE is published the full text of the amended mining law, introduced by Senator Stewart of Nevada, which passed the Senate on the 15th inst. 'Tis twenty-eight years since he introduced and had passed in the same body the first general mining law passed by the United States Government.

A Year's Work of the Commission.

The California Debris Commission, with offices in the Flood Building in this city, has about finished the first year's active work. A great deal has been done, and as the satisfactory working of the law becomes more and more apparent, it is probable that even more will be accomplished in the ensuing year. The highest ability and the most conscientious care have characterized the actions of the Commission, and in nearly every instance the results have been commensurate with the efforts made to secure success and mutual satisfaction.

An elaborate system of official statistics is kept, showing the amount of work performed in issuing permits to work hydraulic mines under the provisions of the Caminetti law. For instance, is given a synopsis of the record in the case of the Farrell mine, the second to make application and the first to begin work:

No. 2.—Farrell mine, located near Columbia Hill, Nevada Co.; permit applied for by Eureka Lake and Yuba Canal Co., Consolidated; P. O. Address, Nevada City, Cal. Petition for permit received Aug. 2, 1893; mine drains into Middle Yuba river; nature of proposed dam, earth and logs, twelve feet high, across mouth of old hydraulic pit; approximate capacity, 212,000 cubic yards. Advertised Aug. 18, '94; mine visited by Lieutenant-Colonel Benyard and Major Heuer; meeting held September 4, '93. Then come dates of the order issued, detail plans received, notice of approval; work inspected; by whom permit to mine issued; commenced to work.

Following is a brief summary of information regarding the name, location, ownership, etc., of the sixty-three applications made since the Commission began to receive them:

- 1.—Kelly Hill, Tp. 23 N., R. 6 E., Butte Co.; name of applicant, R. M. Moore, Chico, Cal.; mine drains into tributary of the Sacramento; the approximate capacity of the dam, 200,000 cubic yds.; permit issued, March 27, '94; work began, April 1, '94.
- 2.—Farrell, Columbia Hill, Nevada Co.; Eureka Lake and Yuba Canal Co., Nevada City, Cal.; drains into Middle Yuba; 212,000 cubic yards; permit issued Sept. 9, '93; work began Sept. 13, '93.
- 3.—Omega, Omega, Nevada Co.; M. C. Tully, Stockton, Cal.; South Yuba; 1,000,000 cubic yards; petition received Aug. 16, '93; permit not yet issued.
- 4.—Richmond Hill and Saw Pit Flat, Onion creek, Plumas Co.; Good Hope Mining Co., Oakland, Cal.; Middle Feather; Aug. 25, '93; not issued.
- 5.—Brandy City, Brandy City, Sierra Co.; 1,940,000 cubic yards; Middle Yuba; A. Steinberger, S. F.; Sept. 19, '93.
- 6.—Blue Nose, Pilot Peak, Plumas Co.; 50,000 cubic yards; Middle Feather; B. Below, Oakland, Cal.; Sept. 19, '93.
- 7.—Blue Gravel, Smartsville, Yuba Co.; Yuba; Excelsior Water and Mining Co., Smartsville, Cal.; 2,885,000; Sept. 27, '93; granted Oct. 17, '93; began work Nov. 1, '93.
- 8.—Illinois Gold Gravel Mine, La Porte, Plumas Co.; Yuba; Buckley & Hillman, La Porte, Cal.; 35,000; Sept. 29, '93; Jan. 31, '94; began work April 13, '94.
- 9.—New York Gold Gravel Mine, Tp. 21, R. 12 E., Sierra Co.; Yuba; Westall & Hughes, Sierra City, Oct. 12, '93; Dec. 5, '93; May 1, '94.
- 10.—Corbiere & Bean, Hampshire creek, Butte Co.; 2000; Yuba; Corbiere & Bean, Clipper Mills, Cal.; Oct. 9, '93; Nov. 21, '93; D. C. 1, '93.
- 11.—Phoenix Gold Gravel Mine, Hepsidam, Sierra Co.; Yuba; W. A. and M. E. Schofield, Hepsidam, Cal.; Oct. 14, '93.
- 12.—Eureka Mining Co., Downieville, Sierra Co.; 15,000; Yuba; Eureka Mining Co., Downieville, Cal.; October 16, '93; May 29, '94; May 31, '94.
- 13.—Craycroft Hill Placer Mining Claim, Downieville, Cal.; 21,000; Yuba; Craycroft Mining Company; October 16, '93; May 29, '94; May 31, '94.
- 14.—Excelsior Hydraulic Mining Claim, Downieville; Yuba; Excelsior Mining Co., Downieville, Cal.; Oct. 16, '93; May 29, '94; May 31, '94.
- 15.—Spanish Ranch, Spanish Ranch, Plumas Co.; North Feather; Quincy Mine & Water Co., San Francisco; Oct. 18, '93; 2,000,000; April 14, '94; April 16, '94.
- 16.—Polar Star, Dutch Flat, Placer Co.; 605,000; Bear; John Spaulding, Dutch Flat; Nov. 3, '93; Dec. 13, '93; Dec. 15, '93.
- 17.—A. Denmore, Howard Creek, Sierra Co.; 3100; North Yuba; A. Denmore, Downieville; Nov. 3, '93.
- 18.—Nevada, Gibsonville, Sierra Co.; 6000; Yuba; Geo. W. Cox, Gibsonville; Dec. 12, '93.
- 19.—54 Flat, Volcano, Amador Co.; 72,600; Mokelumne; 54 Flat Mining Co., Sutter Creek, Cal.; Nov. 4, '93; Feb. 6, '94; Feb. 14, '94.
- 20.—Red Hill, Ono, Shasta Co.; 900,000; Sacramento; Nathan Gardiner, Ono, Cal.; Nov. 16, '93; Feb. 6, '94; Feb. 26, '94.
- 21.—Badger, Tp. 30 N., R. 6 W., Sierra Co.; Cottonwood; W. R. Stewart, Igo, Cal.; Nov. 29, '93; Jan. 2, '94; March 11, '94.
- 22.—First Chance, Howard Creek, Sierra Co.; 8690; North Yuba; F. E. Barberio, Sierra City; Dec. 4, '93; Jan. 2, '94; April 23, '94.
- 23.—Tanney Ravine, Challenge Mill, Yuba Co.; 400; Yuba; W. R. Reed, Brownsville, Yuba Co.; Dec. 4, '93; Jan. 10, '94; Jan. 14, '94.
- 24.—Mateos, Howard Creek, Sierra Co.; North Yuba; Manuel Mateos, Sierra City, Cal.; Dec. 4, '93; Jan. 2, '94.
- 25.—Davis, Howard Creek, Sierra Co.; North Yuba; Jos. Davis, Sierra City, Cal.; Dec. 4, '93; Jan. 2, '94; May 7, '94.
- 26.—Christmas Hill, Butcher Ranch, Placer Co.; American; Gilbert & McKinstry, Butcher Ranch, Dec. 5, '93.
- 27.—Walker, Igo, Shasta Co.; Cottonwood; Engle & Walker, Igo, Cal.; Dec. 8, '93; Jan. 31, '94; Feb. 26, '94.
- 28.—North Star, Mokelumne Hill, Calaveras Co.; Mokelumne; McGuire & Havens, San Francisco, Dec. 13, '93; Jan. 10, '94; Feb. 10, '94.
- 29.—Hustler, Cherokee, Nevada Co.; South Yuba; 210,000; J. Hustler, Patterson, Cal.; Dec. 17, '93; Jan. 23, '94.
- 30.—Green Mountain, Mokelumne Hill, Calaveras Co.; Calaveras; 170,000; J. W. Smith, Oakland, Cal.; Dec. 17, '93; Jan. 8, '94; April 11, '94.
- 31.—Noonday, Howard Creek, Sierra Co.; North Yuba; Jno. Egbert, Sierra City, Cal.; Dec. 26, '93.
- 32.—Pomeroy, Ono, Shasta Co.; Cottonwood; Engle & McGregor, Igo, Cal.; Dec. 26, '93.
- 33.—Union, La Porte, Plumas Co.; Yuba; D. W. Albert, Brownsville, Cal.; Dec. 26, '93; Jan. 31, '94; Feb. 26, '94.
- 34.—Weib Placer mine, Carbonade, Sacramento Co.; Cosumnes; 300,000; Columbia Gold Mining Co., Michigan Bar, Cal.; Dec. 27, '93; Feb. 10, '94; Feb. 13, '94.
- 35.—French Corral, French Corral, Nevada Co.; South Yuba; Kate Hayes Mining Co., San Francisco; Dec. 27, '93; Mar. 13, '94.
- 36.—Manzanita, Sweetland, Nevada Co.; Yuba; Kate Hayes Mining Company, San Francisco; Dec. 27, '93; May 1, '94; May 3, '94.
- 37.—Campo, Brownsville, Yuba Co.; Yuba; Tonsten & Campo, Brownsville, Cal.; Dec. 29, '93; Mar. 7, '94.
- 38.—Herring Ravine, Brownsville, Yuba Co.; Yuba; J. M. Wetmore, Brownsville, Cal.; Jan. 10, '94; Mar. 7, '94; Mar. 13, '94.
- 39.—Conduit Ravine, Brownsville, Yuba Co.; Yuba; W. W. and W. A. Lemon, Forbestown, Cal.; Jan. 21, '94; Mar. 27, '94.

- 40.—Motor, Brownsville, Yuba Co.; Yuba; Jas. Gordon, Brownsville, Cal.; Jan. 21, '94; Mar. 7, '94.
- 41.—Spring Gulch, San Andreas, Calaveras Co.; Calaveras; J. S. White, San Andreas; Jan. 31, '94; Mar. 13, '94; Mar. 17, '94.
- 42.—Crane Bros., Brownsville, Yuba Co.; Yuba; Crane Bros., Brownsville, Cal.; Feb. 5, '94; Mar. 7, '94; Mar. 10, '94.
- 43.—Indian Hill, Spanish Ranch, Plumas Co.; 175,000; Feather; Lazier & Eyrand, Spanish Ranch, Cal.; Feb. 6, '94.
- 44.—Badger Hill, Spanish Ranch, Plumas Co.; Feather; 2,000,000; E. B. Jacks, Meadow Valley, Cal.; Feb. 7, '94.
- 45.—Snow Bros., Newtown, El Dorado Co.; American; 161,333; Snow Bros., Newtown, Cal.; Feb. 13, '94; Apr. 3, '94; Apr. 9, '94.
- 46.—Green Meadow, Glencoc, Calaveras Co.; Mokelumne; H. B. Havens, San Francisco; Feb. 15, '94; Apr. 11, '94; May 1, '94.
- 47.—Grub Flat, Meadow Valley, Plumas Co.; Feather; Tucker & Brown, Meadow Valley, Cal.; Feb. 15, '94; Apr. 1, '94; Apr. 11, '94.
- 48.—Oriental & Tahoe, Randolph Flat, Nevada Co.; Yuba; Jas. Hackett, Rough & Ready, Cal.; Feb. 16, '94.
- 49.—Eureka Hydraulic, Placerville, El Dorado Co.; American; Pascoe and Grenben, Placerville, Cal.; Feb. 19, '94; Apr. 10, '94; Apr. 12, '94.
- 50.—Spanish Hill Hydraulic, Placerville, El Dorado Co.; American; El Dorado Water & Deep Gravel Mining Company, Placerville, Cal.; Feb. 19, '94; Apr. 10, '94; Apr. 12, '94.
- 51.—Spanish Hill Gravel, Placerville, El Dorado Co.; American; 750,000; Thos. Alderson, Placerville, Cal.; Feb. 19, '94; Apr. 10, '94; Apr. 12, '94.
- 52.—Cleveland, Scales, Sierra Co.; North Yuba; 256,000; Douglas Perkins, San Francisco; Feb. 24, '94.
- 53.—Dutra, Wilder & Co., Dobbins, Yuba Co.; Yuba; 4444; Lewis Wilder, Dobbins, Cal.
- 54.—Mitchell Hydraulic, Placerville, El Dorado Co.; American; R. & J. Blair, Placerville, Cal.; Mar. 7, '94.
- 55.—Stewart Hydraulic, Placerville, El Dorado Co.; American; 7790; Jno. Melton; Apr. 3, '94; May 1, '94.
- 56.—Richmond Hill, Onion Valley, Plumas Co.; Feather; 150,000; Good Hope Mining Co., Oakland, Cal.; Mar. 30, '94.
- 57.—Saw Pit Flat, Onion Valley, Plumas Co.; Feather; 150,000; Good Hope Mining Co., Oakland, Cal.; Mar. 30, '94.
- 58.—Onion Valley Creek, Onion Valley, Plumas Co.; Feather; 150,000; Good Hope Mining Co., Oakland, Cal.; Mar. 30, '94.
- 59.—Nip and Tuck, Bangor, Butte Co.; Feather; 5000; Dickhouse Bros., Bangor, Cal.; Apr. 9, '94.
- 60.—Concordia, Cromberg, Plumas Co.; Feather; 75,000; L. V. Tefl, Cromberg, Cal.; May 16, '94.
- 61.—Northern Placer, Cromberg, Plumas Co.; Feather; Northern Placer Mining Co., Cromberg, Cal.; May 16, '94.
- 62.—Schuyler, Igo, Shasta Co.; Sacramento; Thos. White, Igo, Cal.; June 5, '94.
- 63.—Hayes & Steelman, Sierra City, Sierra Co.; Feather; Philip Hayes, Sierra City, Cal.; June 12, '94.

Production of Gold in the United States.

In his annual report of the production of precious metals Director of the Mint Preston makes the statement that the production of gold in the world in 1893 was the largest ever known.

Mr. Preston estimates the approximate gold yield of the mines of the United States in 1893 at \$35,955,000, as compared with \$33,014,981 in 1892, an increase of \$2,940,019. The United States still holds the first place in the list of gold-producing countries.

Mr. Leech, Mr. Preston's predecessor, estimated the silver production of the United States in 1892 at 58,000,000 ounces, of the coining value of \$74,898,900. Mr. Preston, in the statement sent to Congress, follows the method by which the silver production of the United States had been estimated for a series of years prior to 1892. The result is a revision of Mr. Leech's figures, Mr. Preston placing the output of our silver mines in 1892 at 63,500,000 ounces, of the coining value of \$82,101,110, an increase over 1891 of 5,175,000 fine ounces, of the coining value of \$6,684,444. Our silver production in 1893 Mr. Preston estimated at 60,000,000 ounces, of the coining value of \$77,575,757.

The imports of gold into the United States during 1893 consisted of \$14,700,847 in foreign bullion; \$23,439,868 in foreign coin; \$578,186 in foreign ore.

Imports of United States gold coin aggregated \$34,621,673, making the total imports \$73,280,575.

The gold exports in 1893 were \$80,010,633. Of this sum \$71,995,129 was United States gold coin.

Foreign gold coin and ores of the value of \$7,518,153 were re-exported. The balance of the gold exports consisted of United States bars, domestic bullion, gold contained in copper matte and domestic ores.

The imports of silver into the United States for 1893 aggregated \$27,765,696.

The exports aggregated \$47,463,390, the exports thus exceeding the imports by \$19,697,694.

The consumption of gold in the industrial arts in the United States in 1893 is estimated at \$13,435,901, and of silver at \$9,634,277.

The most remarkable facts brought to light in the report on the production of the precious metals in 1893 are: That the world's output of gold in 1893 is the largest in history, amounting as it did to 16.08 per cent more than the annual average of the period of the greatest productiveness of the Californian and Australian gold mines; that the value of the gold product of the world in 1893 was only 8.77 per cent less than that of the average aggregate gold and silver production of the world in 1861-1865; that the average of the total gold and silver production of the world for the period of eight years—1866 to 1873—which just preceded the beginning of the depreciation of silver, was only \$35,309,000 more than that of the gold output alone of 1893. There is also a great probability, amounting almost to a certainty, says Mr. Preston, that the value of the world's output in 1894 will equal that of both metals in the years 1861-65, and in 1895 or 1896 it will equal that of the years

immediately preceding the beginning of the depreciation of silver, that is, the average of 1866-73, inclusive; and that in 1897 it will be greater than such average; that the value of the gold alone available in 1893 for monetary purposes was greater than the total value of both gold and silver available for monetary purposes in the years just preceding the beginning of the depreciation of silver.

Concentrates.

THE Horn Silver mine is weekly shipping 300 tons of ore. TWENTY-NINE Montana mines have paid dividends to date aggregating \$28,034,727.

THE April gold output of the Witwatersrand, South Africa, district was 168,745 ounces.

'Tis reported around Sutter creek that Alvinza Hayward is about to buy the Gover mine.

THE Ogdan-San Juan Mining Company has incorporated at Ogden, Utah. Capital stock, \$40,000.

THE bill for the extension of one year on the assessment work on mining claims has passed the House.

THE *Record* says Ouray county, Col., is employing 500 more miners at this time than six months ago.

SUPERINTENDENT WAGOONER has begun crushing ore from the Granits Hill mine at the Crown Point mill.

THE hydraulic mine on Hungarian Hill owned by the Plomss Imperial Gold Mining Company is in operation.

FRANK POWELL, a mining superintendent at La Joya, Oaxaca, Mexico, was killed by three Indians recently.

CHARLES W. STEELE, manager of the Independence mine at Colorado Springs, who accidentally shot himself, is dead.

THE Lovelock *New Era* has been moved to the new mining camp, Kennedy, and will begin publication immediately.

THE gold receipts at the Denver Mint for the month of May were \$431,934, as against \$99,736 for the same month of 1893.

THE Kansas City & Cripple Creek Mining Company has been incorporated at Cripple Creek, Col. Capital stock, \$1,000,000.

THE Denver & Gueniesine Mining Co. has been incorporated at Denver. Capital stock, \$125,000. The mines to be worked are in Mexico.

MAJ. L. C. MOSELMAN has sold a half interest in the Nugget and Sunrise mines, San Bernardino county, for \$40,000, and stock for \$15,000.

THE new quartz mill at the Livingston mine, San Bernardino county, is in operation. The clean-up of the first five tons of ore netted \$372.

THE Old Dominion Copper Company of Globe, Arizona, closes down to-day "till Lake copper recovers to ten cents"—a remote contingency.

WYOMING men think they have discovered near Atlantic a whole mountain of copper ore bigger and better than the Anaconda, Montana, deposit.

THE Pliocene Mining Company, to operate mines in Shasta county, has incorporated with capital stock of \$100,000. Sacramento is the principal place of business.

A NEW deposit of anthracite coal has been discovered near Ouray, Colorado. In 1892 the anthracite production in that State was 62,303 tons, all from Gunnison county.

IT is but recently Lucky Baldwin sold the Gold Mountain mine to Burt Dooper for \$40,000. The latter is reported to have bonded the mine to an English company for \$500,000.

CRIPPLE CREEK's latest infiction is from a plague of caterpillars. They have eaten the leaves off the trees, fill level the ruts in the roads, and are two feet deep in old prospect holes.

NO. 3 SHAFT of the Tamarack copper mine, in Michigan, has reached a depth of 4320 feet. It is thought to be the deepest mining shaft in the Union. Shaft No. 2 is only 175 feet behind No. 3.

THE \$32,000 attachment on the Sutro tunnel for legal services by San Francisco attorneys, may, it is thought, occasion a change in the control of the tunnel, which cost \$7,000,000 to bore.

THE Omaha Mining Company declared two dividends this month—Nos. 27 and 28, and for 15 cents per share each. Superintendent Mainhart says that the mine is looking as well as ever.

THE twenty-seven miners who attacked the deputy sheriffs on Bull Hill in February are being tried in Colorado Springs. THE *Record* says the criminal docket of El Paso county is a hummer.

C. A. STOCKTON, President of the Standard Gold and Silver Mining Company, who was charged with forgery, has been freed from custody, and will sue for damages the parties causing his arrest.

WORK on the China Creek mines of British Columbia is being resumed. The King Solomon mine is worked by a large party. A few days ago a button was taken from the mine valued at \$380.

ANOTHER alleged gold discovery is reported at Red Rock, thirty miles from Mojave. This time one man secures \$170 in one day by the dry washer process. Water is said to be had "in unlimited quantity" at the Bonanza mine.

THERE is considerable mining interest developing in Lane county, Oregon. In a district 25 miles east of Cottage Grove there is some attention given to gold quartz discoveries, and there are two properties there that are milling \$100 ore.

CREDITORS of the Gover Mining Company of Amador have petitioned to have the corporation declared insolvent. The petitioning creditors complain that the corporation has permitted its property to remain under attachment since May 25th.

THE Seattle *Post-Intelligencer* says that if you pound a \$20 gold piece into a lump it is still worth \$20, while if you pound 20 silver dollars into a lump they are worth less than \$10. It might have added that if you pound a \$20 greenback into a lump it is worth nothing at all.

THE *Dispatch* hears that a heavy lawsuit is brewing between the Argonaut and Kennedy Mining Companies. The former

claims that the latter has been operating within its lices to the extent of some 40 feet, and it is said will demand restoration of the ore taken from rock extracted therefrom.

AN interest in the Mercur Gold Mining and Milling Company has been sold by its owner, J. H. Hedges, one of the former directors of the company, for \$150,000. He owned 23,000 shares of the capital stock, and his holding was purchased by President Dern and two of the other stockholders.

HOONOO is lively at present. It is within the Government reserve, which embraces the headwaters of the Palouse, the Potlach and the St. Mary's. Three bears were lately killed there in one day. There are over 100 miners there, and they get fifty cents to the pan in the ground sluice, so it is said.

A SINGULAR accident happened near Boulder, Montana, last Tuesday. A rock weighing a ton was loosened by the heavy rains and, crashing down the mountain, struck square over the mouth of the shaft of the Katie mine and fell to the bottom, mangling two miners working there. The shaft was a hundred feet deep.

THE old Pisco gold quartz mines, near Yuma, comprising the Mars, Venus, St. Georges and Goshen mines, including the 15-stamp quartz mill built by the late David Neahr, and which cost \$40,000, has been sold by J. M. Meudevil, agent for the owner, D. W. C. Jones of New York, to Col. S. K. Allen and his associates, a Chicago syndicate of capitalists, for \$125,000.

F. CHAPPELLET has recently acquired the El Encino mine, containing over a mile of the blue gravel channel in Chile gulch, three and one-half miles south of Mokelumns Hill. A drain tunnel is to be run 1000 feet. The company owns one-half mile of the Chile Gulch below the mine location for tailings, and expects to have the tunnel finished by November 1st.

THE Amador county assessor has raised the assessment this year of a few of the mines which have been idle for many years and has been assessed at a nominal figure. The Hector of Sutter Creek has been raised from \$12,000 to \$20,000; the Consolidated Amador Quartz Mining Company, this side of Sutter Creek, from \$5000 to \$21,400; the Lincoln Gold Mining Company, just beyond Sutter Creek, from \$5000 to \$18,200.

THE Idaho *Avalanche* says: Exaggerated reports of the prosperity of Owyhee have been circulated, which is leading to an uncalled for influx of working men, who find upon arrival that the chances for employment are not as numerous as they are anticipated. There are now more miners and laborers in Silver City and DeLamar than can obtain work. Living is high there and parties without resources should keep away.

THE Butte, Anaconda & Pacific Railroad will be built this season into Granite, Ravalli and Missoula counties, Montana. Work will be begun next week. It is thought three thousand men will be put to work. The route is via Phillipsburg and down the Shalako into the Bitter Root valley to a point twelve miles south of Missoula, where it will cross the Bitter Root river, entering Missoula across the flat southwest of the city.

THIS advice is from the Winnemucca *Silver State*: Don't rush to Kennedy for employment at wages. The labor market is supplied. If you have elastic muscles, bacon and beans, there is plenty of room for finding a good mine. A large scope of inviting country lays all around awaiting your coming, and with industry you are liable to find it rich. Industry alone found Kennedy, and industry is the only thing that pays down there.

THE Georgetown *Courier* unkindly says it is stated that several mines at Cripple Creek have been operated on a plan very similar to that of the Holy Moses at Creede. Georgetown miners state that they have seen trains of cars leave Creede with ore from the Holy Moses, which was dumped along the track some miles away. This would immediately be followed by an announcement in the Denver papers of "Twenty cars of high-grade ore shipped from the Holy Moses yesterday!" Of course the owners knew nothing about this. Their business was to sell the mine and unload stock, in which they were eminently successful, thanks to the immense output of hallast.

THE following incorporations have filed articles with the Secretary of State at Sacramento:

Stanley Mining Company, San Francisco. Capital stock, \$100,000, with the following directors: G. W. Osborn Jr., G. W. Osborn, San Francisco; W. C. Stanley, Canyonville, Or.; P. H. Kane, Oakland; N. A. Brady, Mountain View, Cal.

The Granite Gold Mining Company, Sacramento. Capital stock, \$600,000, with Kate L. S. Cummings and George W. Cummings, of Placerville, and William Schaw, J. O. Coleman and H. R. Martin, of Sacramento, as directors.

Loris Gold Mining Company, Pasadena. Capital stock, \$300,000, with the following directors: George W. McGee, Chicago; Edward Kennedy, J. O. Macament, Jesse H. Dickey, Newell W. Bloss, Pasadena.

REPRESENTATIVE SWEET of Idaho has secured the passage of his bill by the House to amend the laws relating to mining claims. This bill is similar to the bill introduced by Bell of Colorado, which passed the House at the extra session, except that Bell's bill suspended the operation of the law requiring \$100 worth of work to be performed annually on mining claims located since May 10, 1874, for the year 1893, while Sweet's bill suspends the law for 1894. It was claimed that Bell's bill passed the House so late in the year as to be of little benefit to miners. There was a great deal of opposition to the bill from sections in which mining corporations own a large number of claims, and South Dakota and the Second Congressional district of Colorado were exempted from the provisions of the law.

CAENA'S CREEK, emptying into the Columbia river about 30 miles north of Revelstoke, is the first of the famous gold creeks crossed by the trail leading to the Big Bend gold country. The Big Bend of the Columbia is that portion of the river lying north of the Canadian Pacific Railway, which crosses the Selkirk mountains from Donald to Revelstoke, the river forming two sides of a nearly perfect triangle, with the railway as its base, Canoe river being at the northern apex. Gold abounds in nearly all the creeks flowing into the Columbia in this bend or triangle, but the best finds have been made on creeks flowing into the big river on the western leg of the triangle, where it is flowing southward after doubling back on itself from the sharp turn at Canoe river. Chief among these tributaries is Gold stream, so called from the fact that some two or three million

dollars' worth of gold nuggets and coarse grains were taken out in the boom days of '65 and '66. At the present time French and McCulloch creeks, both flowing into Gold stream, are being profitably worked by several small companies, notably the Consolidation and Vandal claims on French creek, the former averaging about \$1400 a month for each man employed for the last ten months. Carne's creek derives its name from a miner named Carne, a Cornishman, who is reported to have taken out a lot of money, variously stated to have been all the way from \$1500 to \$15,000, from the first half-mile of the creek from its confluence with the Columbia.

THE Georgetown *Courier* grows reminiscent, and says: About six years ago J. F. Seymour, J. L. Sanderson and W. G. Pell, owners of the Slide mine in Boulder county, employed Ernest LeNeve Foster to make a report upon the mine, showing it to be worth \$750,000. Mr. Foster, having had experience in making a similar report upon the Astor mine, readily undertook the job, looked into his crystal sphere, and made a report which evidently convinced some Loudon bankers that the property was cheap at three-quarters of a million of dollars, so they purchased it. Whether they are satisfied with the bargain to-day, or whether they are in the boat with the Astor owners, has nothing to do with the suit that Mr. Foster has just brought against the original owners of the Slide mine for \$25,000, for making that report.

THE approximate gold yield of the United States in 1893 was 1,739,325 fine ounces, valued at \$35,955,000, as compared with 1,597,100 fine ounces, valued at \$33,014,981, in 1892. The United States still holds first place in the gold-producing countries of the world. In '93 the silver output was 63,500,000 fine ounces, of the coining value of \$82,101,110. The total African product in '93 was \$29,305,755. The world's production of the precious metals in 1892 was \$146,297,600 in gold; in silver, \$197,230,500, showing an increase over 1891 of \$15,647,600 in gold, and in silver of \$20,274,600. The world's production of gold in 1893 is estimated at \$155,521,700, showing an increase over 1892 of \$9,224,100. The world's silver output of 1893 was \$207,895,400, an increase over that of 1892 of \$10,664,900. The world's output of gold in 1893 is the largest in history. The value of the gold alone available in 1893 for monetary purposes was greater than the total value of both gold and silver available for monetary purposes in the years just preceding the beginning of the depreciation of silver.

Clipped and Condensed.

MORE attempts are reported against the Russian Czar's life.

THE deficit for the fiscal year ending to-day is estimated at \$74,500,000.

THERE have been over 2,000,000 admissions to the San Francisco Exposition to date.

TWO experts will next week conduct the annual inspection of the San Francisco mint.

THE Northwest Interstate Fair will open at Tacoma, Wash., August 15th and close November 1st.

ONE HUNTER AND EIGHTY miners lost their lives by an explosion in a coal pit near Glamorgan, Wales, last Saturday.

THE latest from the tariff bill show that sugar, coal and iron will be protected. Wool and lumber will probably go on the free list.

ANLT-GRNL. TAASRAY of Colorado was tarred and feathered by masked men at Colorado Springs last Saturday night, and warned not to return under penalty of death.

CAENOT, the President of the French republic, was assassinated at Lyons, France, last Sunday night by an Italian anarchist. He plunged a dagger in President Carnot's heart, the wound speedily proving fatal. M. Casimir Perrier was on Wednesday last elected as his successor.

A. R. HAMMON, with a party of twenty-one miners, left New York yesterday to prospect in Mashonaland and other South African countries. After arriving at Cape Town they expect to go to Beria, on the east coast, 1600 miles to the north, and will travel 600 miles inland to the new gold fields.

Personal.

J. A. CONLON has been re-elected superintendent of the Conlon Mining Co.

A. A. GIONAN of the Texas Hill mine, El Dorado, is in the city to buy additional machinery.

W. F. BREMAN of Globe, Arizona, is in the city buying machinery for his gold-mining properties near Globe, Arizona.

THE following is from the New York *Engineering and Mining Journal*:

A company has been registered in London under the name of "The Sherlock Gold Mines, Limited," to acquire the Sherlock mines, which comprise the W. Y. O. D., Omaha, North Star and Wisconsin mines, situated in the Whitlock mining district, Mariposa county, California. The capital is £60,000 in £1 shares. The directors are Messrs. C. H. Tindal, W. B. Smlth, W. Chatwin, F. Spencer and D. L. Baumgarten.

There is a Whitlock mining district in Mariposa county, with several good mines worthy of development by capital from London, or anywhere else, but the mines named above are in Nevada county, and so far as known are not for sale. London investors would do well to make inquiry before picking up any of that \$300,000 stock on the strength of the names given.

THE miners of Mercur, Utah, resolved as follows: "That it is the sense of the miners of this meeting that it is impolitic and against the real interest of the miner and the mining industry for Congress to exempt mining claims from manual labor." The resolution of the Mercur miners would have more force if they adduced some good argument in favor of the assumption. Men who have given the subject considerable study think just the other way.

Santa Catalina.

As the mainland of California advances in population and importance in the eyes of the world, the attractions of its environment naturally become better known and appreciated. This remark is especially true with reference to the picturesque islands which lie off the coast of southern California and add so much to the beauty of the ocean views westward from the mainland. Until within the last decade these islands were only viewed from this distance, except by fishermen and goat-herders and scientific explorers. Their characteristic charms of scenery and climate were unknown to the public, except by hearsay. Recently, however, there has been an enterprising effort to make some of the islands more accessible and available for public enjoyment, and at present Santa Catalina island may be counted among the leading popular resorts of the State.

The views on this page give some suggestion of the delights of Catalina—the variety of its scenery, which includes both peaceful bays with bathing beaches; bold, rocky shores, against which at times the waves dash with charming fury; and picturesque canyons and dells, with lovely limpid streams and waterfalls. All these features are embodied in the composite engraving which we present, and which weaves together the best parts of half a dozen photographs.

Santa Catalina island lies in the Pacific ocean, about 25 miles southwest of San Pedro harbor, in Los Angeles county. It is approximately 25 miles in length, and perhaps 6 miles in width at its widest part, but throughout its greatest length it is but 1 to 3 miles from side to side. This gives the island a long shore line and plenty of room for the visitor who likes long walks or sails. There is much of interest, too, both in its land and water resources. The water teems with fish, and the land abounds with minerals of great interest and beauty.

Catalina is not only a resort of no little prominence, but is fast coming to the front by adding wealth to our southern country. Valuable quarries of soapstone and serpentine ornamental and building stone have been opened up and are causing great interest among the building community. The serpentine stone is very beautiful, having, on account of its different colored veins, the appearance of onyx. The soapstone quarries are situated in a very romantic part of the island, and it adds to their interest to find old excavations where the Indians quarried soapstone to make culinary utensils more than 150 years ago. Thus early did Catalina pay tribute to the mainland.

Both summer and winter the island is a charming resort. Its climate is much milder than the adjacent mainland. All winter long Catalina is lovely, with its mountains and valleys of green, its still, crystal-like waters, and its beautiful little city of Avaloo, which has an appearance of its own, climate of its own and natural advantages of its own, unlike any place but Avalon. No frosts visit the valley in which Avalon is built, so bananas and other tropical fruit grow there on luxuriant trees, bearing no signs of cold weather.

In calculating "exact time" at the national observatory at Washington, the astronomers do not, as is generally supposed, use the sun as the basis of their calculations. Such deductions are made from relative positions of "fixed stars."

New Process of Gold Extraction.

For some time past a party of Boston capitalists have been down in Nova Scotia establishing a mill on the premises of the Winsor Foundry Company, in Winsor, for the purpose of demonstrating the value of a new process of extracting gold from rock. It is about three months since the men began operations, and during that time they have had their mill at work, and the promoters are of hope. If their process will do what is claimed for it, it is a remarkable thing indeed, and they claim that it has thus far done the work expected.

The new process is a combination of chlorination with amalgamation. The process of extraction is this: The mercury is first combined with salt by the action of elec-

forming the amalgam—another evidence of the power and utility of manufactured lightning.

A New Mexican Mining Law.

A new gold-mining law has been passed by the Mexican Congress.

Contracts will be drawn in the shape of concessions granted by the executive, provided that the data obtained by him justifies him in thinking that actual gold deposits exist within the zone to be explored.

Gold deposits are considered to be not only those of an alluvial character, but those mixed with other ores wherein the yellow metal shall be found in greater proportions as well. As soon as the nature of the ore shall tend to vary from the required average, all contracts will be rescinded.

The concessionaires can, within the area of their zone, acquire the unclaimed mining properties or incorporate in the concession any mining properties they may hold prior to the issuance of their contract. They will be granted exploration privileges that will enjoin any other individual or company from making explorations for any other class of ores, such privilege to last only six months, and not again until the lapse of two years.

All necessary paraphernalia for exploration purposes may be entered free. A rebate from the regular mining tax for a period of ten years, or an exemption from federal taxation for a same period, are the privileges.

In the first three years a capital of \$500,000 must be invested in the enterprise; this is to be increased to \$1,000,000 during the succeeding five years. As guarantee of good faith a bond of \$10,000 must be deposited, to be refunded when evidence is furnished that \$200,000 has been invested.

The concessionaires must establish within two years from date of concession a reduction works capable of handling 400 tons of ore weekly, or some similar establishment of equal value.

THE bill introduced by Senator Power of Montana to amend Section 2324 of the Revised Statutes of the

United States, relating to mining claims, is as follows:

SECTION 1. That the provisions of section numbered twenty-three hundred and twenty-four of the Revised Statutes of the United States which require that on each claim located after the tenth day of May, eighteen hundred and seventy-two, and until patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year, be suspended for three years, so that no mining claim which has been regularly located and recorded, as required by the local laws and mining regulations, and is owned by a bona fide resident of the State or Territory in which said claim is situated, shall be subject to forfeiture for non-performance of the annual assessment for the years eighteen hundred and ninety-four, eighteen hundred and ninety-five and eighteen hundred and ninety-six: Provided, That the claimant or claimants of any mining location, in order to secure the benefits of this act, shall cause to be recorded in the office where the location notice or certificate is filed, thirty days before the expiration of time for completion of the annual assessment work on said claim, a notice that he or they, in good faith, intend to hold and work said claim: Provided, however, That the provisions of this act shall not apply to the State of South Dakota.

SEC. 2. That this act shall take effect from and after its passage.

SCENES ON SANTA CATALINA ISLAND, OFF THE COAST OF LOS ANGELES COUNTY.

tricity, forming a mercurial hydrate of sodium. This is combined with acids, reducing it to such strength that eight ounces of it will impregnate 400 gallons of water. This water is kept in a tank and fed to the mills as the ore is being ground. The ore is ground in this solution, and the instant a particle of rock is parted and the gold relieved, the precious metal instantly comes in contact with the solution and the iron rollers, which relieve the gold by crushing the rock, precipitate the chlorides into the solution, setting the mercury free right at the point where the gold is liberated, causing instantaneous amalgamation. The particles of gold, which are covered with a thin film of mercury, are forced through a large body of metallic mercury, and are there arrested as amalgam. After this the gold is treated in the ordinary manner.

It is claimed that from a barrel of ore sent from Georgia, to be tested in this mill, the amount of precious metal extracted from it was equivalent to \$34 per ton, while tests made by the ordinary stamp mill revealed only \$2 per ton. It is said that a test made with rock that has been used for railroad ballast on one of the roads in the provinces produced gold enough to pay the expenses of working. The real secret of the whole process is the utilization of electricity in

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER V.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894 by Henry G. Hanks, F. G. S.

We find sufficient in history to justify the opinion that the Oracle at Delphi was simply an emanation of natural gas or the vapor of petroleum, which is equivalent to the same thing. The following was published in the London *Lancet* in 1889:

NAPHTHA INTOXICATION.

In several large factories in Germany, especially in India rubber factories and establishments for cleaning India rubber, peculiar morbid symptoms have lately been observed. The faces of many of the girls, who had not left the factory during the day, became flushed and swollen in the evening, and they could not walk steadily. An examination of their clothes and of the work-rooms for kerosene, opium, etc., yielded no result, till an accident led to the solution of the mystery. In these factories naphtha is used in large quantities, and kept in special boilers closed against the air. The girls had succeeded in getting keys to the boiler valves, and soon, learning the intoxicating effect of naphtha, were in the habit of sinking unobserved to the reservoirs to inhale the poison, which threw them into a state of happy forgetfulness and conjured up a thousand sweet dreams of wealth, splendor, happiness, etc. The secret was revealed by a novice, who made too deep an inhalation and fell into hysterical convulsions.

This, in connection with the following quotations from ancient writers, makes a strong argument in favor of such an opinion:

Diodorus Siculus (Book 16, chap. VI) thus refers to the Delphic Oracle: * * * "It is reported that this oracle was first discovered by some goats, for which reason such creatures are sacrificed by the Delphians when they come to inquire of the Oracle. The discovery is related in this manner: There was an opening or gulf in the earth at that place, now called 'the adytum of the temple.' About this the goats straggled as they were feeding, for at that time they of Delphos had no religious regard for the place. It often happened that when any goat came near the gulf and looked down it would fall to leaping and dancing in a wonderful manner and make an unusual noise, far different from that at other times. A shepherd, wondering at the novelty of the thing, drew toward the place to learn what was the cause, and, looking down, he acted the same part with the goats; for, as they were moved and acted as by some enthusiasm, so he was likewise inspired with a spirit of prophesy. The news presently spreading abroad among the inhabitants how wonderfully they were affected that looked down into the chasm, many flocked to the place and out of curiosity made experiments, and as many as came near always acted with a spirit of divination. For these reasons the place was counted the residence of some oracle. For a time, therefore, it was a practice that those who had a desire to know future events would approach the den and there return answers of things that were to come, one to another; but whereas many, through an excess and transport of mind, would leap into the gulf and so were never seen more, it was judged advisable by the inhabitants, to avoid like danger for the future, that some one woman should be consecrated prophetess, and that by her the answer of the Oracle should be delivered, and that an engine should be made for her whereon she might sit, and by that means be inspired without any danger and give answers to them that counselled with her concerning future events. This machine was called the 'tripode,' whose figure and shape almost all the tripodes of brass made up to this day do imitate." * * *

Lucan (Pharsalia, Book 5) relates how Apollus consulted the Oracle of Delphi, which had long been silent, as to the result of the war in which he was engaged. The Oracle is described: He tells how the Temple was opened by Phemonoe, the priestess, who endeavors to persuade Apollus not to inquire into the future. He forces her, however, to seat herself on the tripod. The frenzy of the priestess is graphically described. The following was the ambiguous reply of the Oracle: "O Roman, thou dost escape from the vast threatenings of the war free from dangers so great, and alone shalt thou take thy rest in the wide valley of the Eubœan Quarter." "Then"—in the words of Lucan—"smitten by the breast of the prophetess, the doors open, and, hurried on, she leaps forth from the Temple. Her frantic fit still lasts, and the god, whom as yet she has not expelled, remains in her, not having said the whole. She still rolls her fierce eyes, and her looks wandering over the whole sky, now with timid, now stern with threatening features, a fiery blush tints her face and her livid cheeks, and a paleness exists—not that which is wont to be in one who fears, but inspiring fear; nor does her wearied heart find rest, but as the swelling sea after the hoarse blasts of Boreas, moans; so do the silent sighs relieve the prophetess, and while from the sacred light by which she has beheld the fates, she is being brought back to the sunshine of ordinary day. Shades intervening, come on, Pæon sends Stygian Lethe into her entrails to snatch from her the secrets of the gods. Then from her breast flies the truth, and the future returns to the tripodes of

Phœbus; and, hardly come to herself, she falls to the ground."

At the oil centers in Pennsylvania, to counteract the natural tendency of crude petroleum to evaporate, thinned covers of wood are placed over the oil tanks. These are each provided with a man-hole opening. When the tanks are nearly empty, the smell of gas and oil is very strong, and it sometimes happens that the bodies of men or boys are found, who, in looking into the tanks, have been overcome by the vapors and lie with their faces near the openings. In cases where the effects are not fatal, a kind of intoxication is experienced similar to that described by Diodorus and Lucan, as quoted above.

It is difficult at this distance to understand why the ancients invariably attached superstitious importance to natural phenomena, and the classical scholar is astonished when he reads of the vast treasures donated to this oracle by Crœsus and other wealthy monarchs, a detailed statement of which reads like a fable, although admitted as truth.

Diodorus Siculus (Book 2, chap. I) thus refers to a spring near Babylon which emits a deleterious gas: "Near this fountain there is a spring, not big, but very fierce and violent, for it casts forth a sulphurous and gross vapor which suddenly kills every living creature that comes near it, for the breath being stopped a long time and all power of respiration taken away by the force of the exhalation, the body presently swells so that the parts about the lungs are all in a flame."

Pliny, in his chapter on "Vents in the Earth" (Natural History, Book 2, chap. XCV) refers to gaseous emanations: * * * "The exhalation of deadly vapors, either emitted from caverns or from certain unhealthy districts; some of them fatal to birds alone, as at Soracte, a district near the city; others to all animals except to man, while others are so to man also, as in the country of Sinuessa and Puteoli. They are generally called vents, and by some persons Charon's sewers, from their exhaling a deadly vapor. Also at Amsanctum, in the country of the Hirpini, at the temple of Mephitis, there is a place which kills all those who enter it. And the same thing takes place at Hierapolis in Asia, where no one can enter with safety except the priest of the great Mother of the Gods. In other places there are prophetic caves where those who are intoxicated with the vapor which rises from them predict future events, as at the most noble of all oracles—Delphi." * * *

Book 2, chap. CX-CXI: "In Nymphæum there issues from a rock a fire which is kindled by rain. It also issues from the waters of the Scantia. This is indeed a feeble flame, since it scarcely passes off, remaining only a short time on any body to which it is applied. An ash tree, which overshadows this fiery spring, remains always green. * * * The plain of Babylon throws up flame from a place like a fish pond an acre in extent. * * * There is also the crater of Nymphæum which is always burning, in the neighborhood of a cold fountain, which, according to Theopompus, presages dreadful calamities to the inhabitants of Apollonia. It is increased by rain and it throws out bitumen, which, becoming mixed with the fountain, renders it unfit to be tasted; it is at other times the weakest of all the bitumens."

The following account of the burning gas emissions at Modena, northern Italy, is from "Travels in the Two Sicilies," by Spallanzani, 1788—Introduction, Vol. I:

"The fires of Barigazzo, which burn on the Apennines of Modena, have long been known. These consist of groups of feeble flames collected in a narrow space which rise above the earth, are almost always visible, and if by chance they become extinct, may be rekindled by bringing a small flame to the spot where they were. The accounts of them are so few and so defective that at most they can only serve to compare the present state of these flames with what it once was. The light afforded by modern physics enables us to affirm without further examination that the cause of this feeble fire must be hydrogenous gas (or inflammable gas). I made a journey to Barigazzo purposely to ascertain this, and found it to be a fact. In that vicinity there are six other similar fires at the present time, only known to the Alpine peasants, all originating from the same principle. * * * And here I must observe, by the way, that having made at Barigazzo an excavation of some depth and size, in order to obtain the earth pure, the fires multiplied so much and became so powerful that after I had left the place, the hollow was employed as a furnace for lime, and limestone as perfectly burnt as in furnaces prepared for that purpose. * * * It is certain from authentic documents that these fires have burned for a century and a half."

It has been asserted that the burning gas spring at Sulphur creek in Colusa county, California, will re-ignite if extinguished. If this be so, the fact may account for gas fires burning so continuously.

Gas wells are common in China and have been in use

for many centuries. The gas has been from the earliest times conducted in pipes of bamboo and burned as at present in the United States.

Mines on the Lower Colorado River.

Taylor D. MacLeod in Yuma Times.

Castle Dome.—The mines are situated on the flat mesa and rolling hills near the base of a lofty mountain range, here forming a horseshoe curve. A system of three parallel veins cuts through the country at the outer points of the curve with an N. W. and S. E. strike, and at an elevation above sea level of 1800 feet. They are readily accessible over hard, level mesa roads and "wash," 20 miles from Castle Dome Landing on the Colorado river, thence 30 miles to Yuma by steamer or wagon road; or to Gila City, a station on the S. P. R. R., all road and one handling of ore saved—a distance of 30 miles. Present transportation rates to Castle Dome Landing by team are \$6; thence by steamer and rail to San Francisco \$9, or a total of \$15 per ton; Gila City \$7, team \$8, rail \$15.

The country formation is porphyry. The mines lie in a contact of porphyry and granite, with a dip generally to the east of 45 degrees. The ledges are from two to four feet wide. The vein stuff is decomposed porphyry. The mineral, argentiferous galena and lead carbonates, are in a gangue of fluor and calcspar, with considerable iron oxide. It is a clean smelting ore, carrying no deleterious base material. It is cheaply mined, but little powder required, and that of a "slow," low-grade kind. The ore ranges in value from 20 to 90 ounces silver and 60 to 80 per cent lead per ton.

These mines, under the old regime, yielded steady, remunerative shipments for about 20 years, when work was stopped at a water level 300 feet in depth. The veins of this district in no instance pinch out; they continue and in ore where work was suspended. It probably cost too much at the then price of lead to mine and extract ore 200 and 300 feet deep by hand windlass or whim, though this is the present way of hoisting. Advised by some of the old-time workers in these mines of the location of favorable indications of ore, the present owners have uncovered large ore bodies in virgin ground above water level, and the result is a steady and assured output.

The number of men actually employed at the mines is above 100, and three ore teams are constantly on the road. The Hodges Bros. are operating Washington group; Frank Avila and John Stoffela are shipping from the old Pocomontas and Arkansas mines, and a large force is on Frank Vomocil's Railroad group of eight claims.

Eureka.—Twelve miles north of Castle Dome Landing is found the Eureka district and mines. Extensive work was done here before the advent of the railroad to Yuma. It is exceptionally situated for cheap mining. The outside mines are not one mile from the river bank, and those now working not one-fourth of a mile off.

Here the mountains rise abruptly to a greater height than any other range on the lower river, thus allowing economical working by tunnel. The formation is block slate. The ledges are of a width of two to five feet, between firm walls with a strike N. W. and S. E. Gangue matter is of limestone and quartz and a clay gouge or casing on the hanging wall, dipping to the east and under the mountain at 46 degrees. The ore is silver-lead with seams and pockets of iron oxides, and "free" until water level is reached, when some zinc blende is found in seams paralleling the galenite. Water is found at river level. A hand pump handles the inflow in shaft sinking. At present, as in the past, there is plenty of virgin ground to exploit above the water level, that is responding favorably to tribute workers now on the ground. The ore averages 50 ounces silver and 60 per cent lead per ton. Sufficeth it to say that the Vomocil group, with the Mina Alta, an outside vein strong in ore, comprise the mines of this district. They have supported 60 to 100 people, and shipments are regular. Below Eureka proper, one mile away, Charlie Thiesen has a claim from which he has made shipments in times past.

Azure King Group.—Two miles north of Eureka and half a mile from the steamer landing is situated the Azure King group of six claims. This is a gold-silver-copper proposition, was worked extensively, and ore shipped via the river and Gulf of California to San Francisco in an early day. There are numerous shafts on the vein from 20 to 60 feet deep, in which the notched pole ladders yet in the shafts show the primitive method used in packing out ore and waste on the backs of men in days long since. The mines are situated just within the porphyry mountain range that parallels the river.

The veins have an N. W. and S. E. trend, are two to six feet wide, with a quartz gangue in the talcose-schist vein matter. The copper occurs as a chalcite copper glance; tetrahedrite, gray copper, sparingly; cuprite, red copper; and generously of malachite and azurite, or green and blue carbonates of copper—hence the name.

Crude hand sorting of the vein as it runs returned an

assay value of: No. 1—gold, \$47.54; silver, 15 ounces; copper, 12 per cent. No. 2—gold, \$24; silver, 16 ounces; copper, 13 per cent. It is safe to assume an average value of \$12 gold, \$10 silver and 10 per cent copper to the ore in place.

These claims will be worked at a profit some day, as they are exceptionally easy of access and free, containing not a trace of arsenic, and can be cheaply mined and treated on the ground. Handsome specimens containing coarse free gold imbedded in malachite are not uncommon.

The Haunted Swing.

A good many of the hundreds of thousands who visited the Midsummer Fair in this city were considerably mystified by the apparent "upside down" sensation given them in the "haunted swing."

An article in the current number of the *Scientific American* explains the trick: Those who are to participate in the apparent gyrations of the swing—and there may be quite a number who enjoy it simultaneously—are ushered into a small room. From a bar crossing the room, near the ceiling, hangs a large swing, which is provided with seats for a number of people. After the people have taken their places, the attendant pushes the bar and it starts into oscillation like any other swing. The room door is closed. Gradually those in it feel after three or four movements that their swing is going rather high, but this is not all. The apparent amplitude of the oscillations increases more and more, until presently the whole swing seems to whirl completely over, describing a full circle about the bar on which it hangs. To make the thing more utterly mysterious, the bar is bent crank fashion, so that it seems demonstrably impossible for the swing to pass between bar and ceiling. It continues apparently to go round and round this way, imparting a most weird sensation to the occupants, until its movements begin gradually to cease and the complete rotation is succeeded by the usual back-and-forth swinging, and in a few seconds, as the children say, "the old cat dies." The door of the room is opened and the swinging party leave. Those who have tried it say the sensation is most peculiar and the deception perfect.

The illusion is based on the movement of the room proper. During the entire exhibition the swing is practically stationary, while the room rotates about the suspending bar. At the beginning of operations the swing may be given a slight push; the operators outside the room then begin to swing the room itself, which is really a large box journaled on the swinging bar, starting it off to correspond with the movements of the swing. They swing it back and forth, increasing the arc through which it moves until it goes so far as to make a complete rotation. The

operatives do this without special machinery, taking hold of the sides and corners of the box or "room." At this time the people in the swing imagine that the room is stationary while they are whirling through space. After keeping this up for some time, the movement is brought gradually to a stop, a sufficient number of back and forth swings being given at the finale to carry out the illusion to the end.

The room is as completely furnished as possible, everything being of course fastened in place. What is apparently a kerosene lamp stands on a table, near at hand. It is securely fastened to the table, which in its turn is fastened to the floor, and the light is supplied by a small incandescent lamp within the chimney, but concealed by the shade. The visitor never imagines that it is an electric lamp, and naturally thinks that it would be impossible for a kerosene lamp to be inverted without disaster, so that this adds to the deception materially. The same is to be said of the pictures hanging on the wall, of the cupboard full of chinaware, of the chair with a hat on it, and of the baby. All contribute to the mystification. Even though one is informed of the secret before entering the swing, the deception is said to be so complete that passengers involuntarily seize the arms of the seats to avoid being precipitated below.

Bair's Gold Separator.

Albert M. Bair of Littleton, Colo., has invented an appliance for the separation of fine gold dust from the earth and dross that contain it, consisting of a series of semi-cylindrical or U-shaped sections, joined one within another, the terminal section being the largest and is thickly perforated. Beneath this terminal section is a double-inclined table, covered with a section of Brussels carpet to lodge the gold dust, which is sprayed through with the water. The inner portions of the sections are provided with numerous longitudinal rods. As the water and gold-bearing material passes along, the latter will be screened by the longitudinally extending rods, by the passage of such fine material between them as the spaces will admit. It is claimed that the round shape of the flume materially adds in the collection of gold at its bottom. Such particles of gold as pass through the perforated shells of the sections it is expected will be deposited in the pile of the carpet, or in such other riffle as may be employed, which will be provided with mercury for amalgamation. Owing to the spring supports for the sections, the vibration of the latter, due to the jarring effect of the passing material, will help the separating process. This vibration is wholly automatic. The pile fabric (Brussels carpet) is placed two inches from the perforated shell, so that the water will spray through the shell

onto the carpet, and heat the deposited gold into it. The two outer lower edges of the platform are turned up, to prevent the material from passing off.

Gold-Bearing Rivers.

A new dredge is now in use on the Fraser river, in British Columbia, with plenty of capital behind it. W. A. Shahan, the inventor, recently described it to a Tacoma *Union* reporter.

"The beds of all gold-bearing rivers are covered with a pavement of boulders," said the gentleman. "Through these boulders the gold percolates, they acting the same as riffles in a sluiceway. In fact, the rivers of all placer countries are nothing more than nature's sluice boxes. The gold settles in a stratum of sand lying on the river bedrock and beneath the boulders. By means of a suction pipe so arranged as to telescope and accommodate itself to the depth the bottom of the river is reached. With the immense power given by the vacuum chambers and centrifugal pumps the gravel is drawn through the suction, emptying into sluice boxes fitted with amalgam plates. The boulders are taken care of by two wrought iron baskets so arranged as to work automatically.

"When one basket is filled with debris or large stones it is tripped and emptied, the stream being turned into the other basket. The present suction pipe is eight inches in diameter and has a lifting pressure of 750 pounds at the nozzle. Over the top of the pipe is placed a glass cap. Connecting the air pump the water is forced from the pipe, a submarine electric light dropped, and through the glass the entire bottom of the river is brought into view so closely that in one spot on the Fraser we were able to make out the glitter of gold in the sand.

"The dredge is 75 feet long by 24 feet wide and has cost in the neighborhood of \$10,000. What is needed is that the suction pipe be made two feet in diameter instead of eight inches, with a corresponding increase of power, and then we will be able to handle the largest pieces of slide rock found in the Fraser river bottom."

A surprising amount of activity is being displayed in all of the gold camps of the State, says the *Butte Inter-Mountain*, and Montana promises to lead all other States in the production of the yellow metal during the present year. Never before has the search for gold been prosecuted with such eagerness, and in every canyon and on every hilltop where gold is supposed to exist there are scores of hardy prospectors even at this season of the year. Placer ground thrown aside years ago because it did not pay then, or abandoned to Chinese, is now being worked by miners, and the results are very satisfactory.

Scientific Progress.

Growth of Invention.

It is said of Henry Renwick, the great patent expert, who was the first examiner appointed in the Patent Office at Washington, and who resigned in 1874, that he did so because he had made up his mind that comparatively few more patents would be issued; that the whole field of invention had been pretty thoroughly explored and exhausted, and that he, therefore, thought he ought to look out for some business of a more permanent kind. In commenting on this, a writer in *Cassier's Magazine* says that, at the present day, with the multitude of inventions that have cropped up, and with the host that are to follow, this early view of the subject is uniquely interesting. Experience has more than borne out the statement once uttered that one invention makes at least one additional one necessary. If an article be invented, a machine for making it must often be invented also; the building of this machine may again necessitate the employment of some special tool, for which, too, we may have to depend on inventive genius, and in this way multiplication of devices may go on to an extent little imagined in the beginning. The discovery and manufacture of kerosene for illuminating purposes, for example, are said to have been alone responsible for about 5000 different inventions which have been patented. There are similarly said to be about 3000 separate inventions for coupling railroad cars, and something like 800 for knitting machines. Other equally striking cases would no doubt be afforded by a study of the subject, but are scarcely necessary to complete the picture.

Development of Engineering Science.

Speaking of the development of engineering science in connection with the Brooklyn bridge and the projected bridge across the Hudson river at New York, Representative Geary says:

"A man learns a good many interesting things in Congress. For instance, I am on the Commerce Committee, and we have had a good deal to do with this New York bridge bill. Until the suspension bridge was built across the East river between New York and Brooklyn, it was not supposed that a steel wire could be made of sufficient tensile strength to hold together for a distance of 1600 feet. Until then, with the wire that had previously been made, a wire of that length would part of its own weight. Mr. Roebling, the engineer of the bridge, who was laughed at by other engineers for asserting that a wire of 1600 feet could be made which would hold together, experimented until he proved that his assertion was a fact. Since then the Firth of Forth bridge has been built with wires 1700 feet long, and the making of steel cables has now reached such a degree of perfection that a wire can be made of 2100 feet and strung from one point to another without breaking. In the New York bridge bill we proposed that 2100 feet should be the lowest limit, and now we want to appoint a commission of five engineers, of whom Gen. Casey shall be one, to see if a wire of still greater length cannot be successfully made."

An Interesting Discovery.

Accident recently revealed to the managers of the Baltimore Copper Works a fact which may have some value in refining the metal there handled, says the *New York Tribune*. At this establishment the reverberating furnaces are connected with a great chimney by means of long underground passages, called "culverts," in which more or less oxidized copper, as well as sulphides, arsenides, and other compounds, is carried off in the form of dust and smoke. These are deposited in the culverts, and are subsequently collected to be worked over again.

Amid an accumulation of such stuff, a few days ago, there were found iridescent, moss-like masses, which upon examination proved to be pure copper. How the transformation was effected was a mystery, until it was discovered that petroleum, which saturated the soil in the vicinity (having escaped from a neighboring refinery), had entered the culverts through a crevice. Under the influence of high heat it was volatilized, and the resulting gases had "reduced" the oxides and sulphides into pure metal. It is probable that this revelation will be turned to advantage in future operations.

Weight of a Crowd.

In a paper by Professor Kernot, read before the Victorian Institute, he compared the various estimates as to the weight per square foot of a crowd. One estimate, quoted as French practice by Stoney and Trautwine, gives 41 pounds per square foot of a crowd. Hatfield, in "Transverse Strains," gives 70 pounds; Mr. Page, engineer to Chelsea bridge, 84 pounds; Mr. Nash, architect to Buckingham Palace, quoted by Tredgold, 120 pounds; W. N. Kernot, at Working Men's College, Melbourne, gives the weight at 126 pounds; Prof. W. C. Kernot, at Melbourne University, puts it at 143 1/2 pounds, and Stoney, in his work on "Stresses," as 147.4 pounds per square foot. The space occupied by soldiers, as taken by Hatfield in his estimate, is not the same as a crowd. Soldiers are arranged in lines at a distance apart to allow room for knapsacks and other accouterments; but a crowd is forced together into close contact, an average man in a crowd occupying a space of little if any more than one square foot. On the whole, Prof. Kernot inclines to favor Mr. Stoney's estimate of little more than one man per square foot, and gives it as approved that a dense crowd of well-grown men weighs between 140 and 150 pounds to the square foot.

How Fast the Earth Turns.

Everybody knows that the earth makes one complete revolution on its axis once every 24 hours. But few, however, have any idea of the high rate of speed necessary to accomplish that feat. The highest velocity ever attained by a cannon ball has been estimated at 1626 feet per second, which is equal to a mile in 3.2 seconds. The earth, in making one revolution in 24 hours, must turn with a velocity nearly equal to that of a cannon ball. In short, the rate of speed at the equator has been estimated at nearly 1500 feet per second, or a mile every 3 1/2 seconds, or 17 miles a minute.

MORE than one-half the world's supply of tin is now mined in the Strait's Settlement, says the United States Consul at Singapore. The output in 1891 was 36,061 tons out of a total of 57,551 tons. Of the balance 12,106 tons were mined in the Netherlands, India, leaving but 8384 tons for the rest of the world. For a century up to 1889 the Maylays worked tin by a most primitive method, washing the nodules from the clay and smelting them when dry between layers of charcoal in a clay furnace, fed by bamboo bellows. The molten metal trickled into a vessel, from which it was ladled into molds.

THE water works supplying cities and towns of the United States are reported to represent an investment of \$430,000,000, nearly one-tenth as much as in railroads. The miles of water-mains in New England are nearly equal to the miles of railways. There are only 68 water works in eight Southern States, while the total number of cities and towns in the whole country supplied with water works is about 1700. Probably two-thirds of the supply is furnished by the municipalities, and the balance relies on corporate enterprise.

LOANS AND MINES

Loans negotiated on first-class securities. Mines and mining prospects of guaranteed value sold on working bonds. C. H. DWINELLE, Grand Hotel, San Francisco, Cal.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Mechanical Progress.

The New Atlantis.

The latest idea will soon be put into tangible shape—the building of a summer hotel in the Atlantic ocean.

The exact spot in the ocean where the buildings will be erected has been selected, the soundings made and the location marked by buoys. It is off the Long Island coast, probably somewhere between Fire Island and New York, fourteen miles from the shore. Atlantis will not be built upon a sandbar, nor built over shoal water.

The chief engineer is Captain R. D. Evans, U. S. N., head of the lighthouse board. With him is J. C. McGuire, who has charge of the steel construction in Government buildings. Captain Howard Patterson, formerly of the U. S. N., formerly professor of science in Brown's College, and who was admiral of the Haytian navy, is another of the engineers.

It is said they have agreed to put down the foundations under a forfeit of \$1,000,000. This convinced those who hesitated about putting money into the scheme. The structure will rest upon cylinders. Atlantis will include a number of structures, of which but one will be built this year. It will be a great pavilion, constructed in the form of a square, two stories high in the main and three in the towers, and will rest upon large iron cylinders, filled and sunk in Portland cement.

The main floor will be thirty feet above the water, and the Roman order of architecture will predominate.

The edifice will be built entirely of steel, iron, glass and tiles, thus making it entirely fireproof. Within will be a grand amphitheatre. It is calculated that the lower floor will accommodate 10,000 people, while the gallery will hold 7000 more. There is also provision for a spacious esplanade, or roof garden, seating 3000. There will be 120 large rooms for hotel accommodation, a cafe, restaurant, billiard room and all accessories of that sort. Then there is the anglers' pavilion, which ought to increase the popularity, because the structure will be located in the midst of the fishing grounds. The promoters of the enterprise say it offers all the advantages of a sea voyage without the discomforts of sea-sickness. It is promised that it will be within two hours' sail of New York. It is expected that the building will be opened before the summer is over.

Uniting Wrought and Cast Iron.

When one stands in a blacksmith's shop and sees him fasten together the red hot ends of a wagon tire, with a few skillful blows, it looks like a very easy matter. And so it is, in one sense; and it is rather easy to unite, in the same way, any other pieces of malleable iron. But cast iron has a different grain. It is crystalline and not fibrous, and hence it is impossible to weld it as easily and at the same degree of heat as wrought iron. In fact, many blacksmiths consider it impossible to do so at all. But Jasper Roberson, of Tarkio, Mo., says that he has found a way to weld wrought and cast iron together, and has done so at least three times. In each case the joint was so sound that the articles thus repaired have been in service for over three months without further breakage. Mr. Roberson prefers to keep his method a secret, but he would sell the privilege of using it to others for a reasonable price. It is said, he says, only to objects light enough to be handled in a common blacksmith's forge. Mr. Roberson does not claim to be the only man who ever discovered how to perform this feat; but it is not every worker at the anvil who knows the trick.

A CHICAGO inventor, Paul R. De F. D'Humy, proposes to make armor plate for warships out of two-inch steel cut in strips

of the necessary width, and bolted together so as to present the edges to the enemy. It is argued that this plan puts it in the power of manufacturers having small plants to make the largest plates demanded. But it is not clear how a few bolts can hold the strips together tightly enough to resist a conical projectile so effectually as the cohesion of steel forged in one solid mass.

SCALES big enough to weigh a load of 150 tons have been supplied to Uncle Sam's great gun foundry at Watervliet, N. Y. They are mounted on a car, which can readily be shifted from place to place. The great Krupp gun exhibited at Chicago weighed 130 tons, and therefore would have been a moderate load for this apparatus. The tendency in ordnance nowadays being toward less enormous pieces than were in favor four or five years ago, it is doubtful if the Watervliet scales ever prove inadequate.

ALUMINUM SCABBARDS for bayonets would have been in Uncle Sam's service ere this, because of their lightness, had the Government been satisfied with any of the soldiers offered for the completion of these articles. Some foreign powers, however, it is said, promise a handsome reward for the discovery of a solder suitable for the purpose.

WILLIAM H. SLATER, of Norwich, Conn., will pay \$60,000 more for his elegant steel steam yacht, built at Bath, Me., than foreign builders would have charged; but he was satisfied that he would get enough better workmanship to make up for the difference in cost. Besides, Mr. Slater is a thorough American.

Infusorial Earth.

William Cann, Jr., agent for the Electro Silicon Company of New York, has let a contract to R. Noce for the extraction of 200 tons of infusorial earth from the Parker and Noe mine in the Chalk Hills northeast of Virginia, Nev. Numerous shipments have been made from the same locality during the past two years, but heretofore the earth was sent by rail to this city, thence shipped to New York via Cape Horn. This shipment will be sent directly overland, if freight rates can be secured low enough. The so-called Chalk Hills are really a vast deposit of silica or infusorial earth, which, for commercial purposes, is ground to powder and put up in two-ounce packages, and in that form is sold for 15 cents a package for polishlog purposes. It has recently been discovered that infusorial earth, when soaked with crude petroleum, is an excellent material for kindling fires, a small block of it less than three inches square, when ignited, blazing with a fierce flame for a period of fifteen minutes.

A Close Call.

Joaquin Miller, the poet, grows reminiscent and says: In the winter of 1894 I was employed to push a tub along a wooden track underground. It was a new tunnel; everything about it new and experimental. The mouth of the low, narrow tunnel opened out toward the sun and the swift, clear Klamath river. I was employed because I was so small. The two men worked on their knees and breasts. On the fifth day the hillside slid in and one of the men was crushed. The water came in. My head was caught up between two timbers, lifting my face above the water. I could hear the man groaning, till the water reached where he lay—then was the end. But as one of the men was out of the tunnel getting timbers and I happened to be near the mouth of the tunnel with my tub at the time of the slide, I was dug out by the man who escaped the same day. I set this down as one example in a thousand that almost any miner might narrate from his underground life in California.

INSTRUCTION BY MAIL

IN ARCHITECTURE, ARCHITECTURAL DRAWING, PLUMBING, HEATING AND VENTILATION, BRIDGE ENGINEERING, RAILROAD ENGINEERING, SURVEYING AND MAPPING, ELECTRICAL ENGINEERING, MECHANICAL DRAWING, MECHANICS, ENGLISH BRANCHES, and

... MINING ...

Diplomas awarded. To begin students need only to know how to read and write. Send for FREE Circular of Information, stating the subject you think of studying, to The Correspondence School of Mechanics and Industrial Sciences, Scranton, Pa.

4000 STUDENTS.

HEALD'S

BUSINESS COLLEGE,
24 POST STREET.....SAN FRANCISCO.
FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing, Book-keeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils. Our school has its graduates in every part of the State. SEND FOR CIRCULAR. E. P. HEALD, Pres. O. S. HALKY, Sec.

PLACER AMALGAMATORS

Combined with Steam Shovel or Dredge.

BUCYRUS SYSTEM.

NEW METHOD OF PLACER MINING.

Saves all the Gold. Uses very little Water. Treats large quantities at Low Cost.

—BUILT SOLELY BY THE—

BUCYRUS STEAM SHOVEL AND DREDGE COMPANY,
SOUTH MILWAUKEE, WIS. U. S. A.

Adamantine Shoes and Dies

—AND—
CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Front St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

DOUBLE ACTING CORNISH PLUNGER.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. Only about one-third the weight of the old plunger. Special construction of steel for picking on mules, only one-twelfth the weight of the ordinary plunger. First outlay one-third less, works with 10 per cent less power.

IMPROVED SINKING PUMP.—Bucket and clack changed under water. Bucket lasts six times as long as the old one, saving expense of putting down another pump where bucket and clack cannot be changed under water. The self-tightening and self-lubricating stuffing box and new bucket also saves expense of dropping extra pumps.

WM. NANCE, Grass Valley, Nevada County, California.

Electric Progress.

"Edison's Town."

It is pretty hard to keep pace with the work Thomas A. Edison is doing. At present everybody is talking about his latest invention, yet very little is known about a town in New Jersey that he owns and which is named after him, and where he is undertaking one of the biggest commercial operations of the age. All that has heretofore been written on the subject has been with reference to the machinery he invented, and with which, by means of magnets, he is reducing high grade iron from low grade ore. Something about the town and its work ought to be of public interest.

Edison is in the mountains, two miles and a half from Ogdensburg. Formerly it was known as Ogden, because the old Ogden mine was there. This mine used to be operated, but it didn't pay and was abandoned. A lot of rickety tenement houses was all that remained of the building. Since Edison took the property, four years ago, great changes have taken place. Electricity, introduced by Edison, is responsible for the wonderful improvement.

Within half a mile seventeen buildings have been constructed, one of them 500 feet long and 100 feet high. Twenty 1200 candle-power arc lights enable night and day shifts to work. A water tower 123 feet high gives sufficient head to make water flow wherever needed, and long-distance telephones enable the superintendent from his office to converse with one in any of the buildings or an agent in Chicago. All work is done on the premises and done systematically, every item of cost being considered and labor-saving devices used. In the carpenter shop, for example, which is 100 feet in length, heavy beams are mortised by circular saws which are operated by electricity and suspended from above, swinging like a pendulum, and the table upon which is the beam to be mortised is raised so that the saw will cut to the proper depth. Adjoining this shop is the stock house, which contains \$100,000 worth of hardware—everything, from a large bolt to a small paper of pins.

The mine is spanned by four mine troyes, each 216 feet in length. To the novice each is a high suspension bridge, the ends upon trucks which run upon car tracks and resting upon the ore in the mine, which is raised in an immense scoop and carried along this bridge and dumped into the car at the end. One lump that lay near the rollers contained 36 cubic feet. This ore is first dumped between rollers six feet in diameter, which drop it to rollers four feet in diameter, and so on from roller to roller until the ore is crushed into half-inch lumps; then it is taken to the dryer and thence to the stock house, 280 feet distant, by means of belts, elevators and buckets like those used in grist mills, except that they are of iron and greater capacity. The moisture remaining in the ore is but one-tenth of 1 per cent. The fine ore is carried upon rubber belts, the edges of which are raised by rollers keeping it in place, into a building 100 feet high, when it is allowed to fall through boxes in which are magnets, and the ore is separated from the dust, the ore coming out at one place and the dirt at another, and is carried either out to the tailing banks or dumped into the cars ready to receive it. The tailings being free from dust make the best of building sand, and is shipped to Jersey City and New York. It is sold for 50 cents a ton, costs $\frac{1}{4}$ cent to dump it directly into cars and 5 cents if taken after deposited on the tailing bank. The advantage of the Edison method is that the bricks of ore will fuse 15 feet higher than in the ordinary furnace, thereby saving largely in fuel. The iron is 68 per cent metallic, while the purest known is 72 to the ton, showing that the ore is of superior quality. The capacity under the old system

was 1000 tons; under the new it will be 5000 tons per day, and 300 men will be required to do the work of 1200 under the old system. The changes, which will be completed in about four weeks, were begun a year ago last September, when 25 per cent of the machinery then in use was thrown out. The improvements will cost \$250,000 and bring out a high grade, clean ore.

Electric Mileage of the United States.

In 1888 the entire electric railway mileage in the United States was only about 48, distributed over eight States. At the close of last year the electric railways comprised 61 per cent of the entire street railway system of the United States, this gain being at the expense of the horse and steam lines. The past year the mileage operated by horse power decreased from 4460 to 3497 miles, and that by steam 640 to 566. The total street railway mileage increased 540, but the electric mileage increased 1517 miles, showing up an extensive conversion of horse line into electric. About one-quarter of the mileage of the horse railways in the United States a year ago has been fitted for electricity. It is predicted this system will be a formidable competitor of the steam railways for suburban traffic.

THE Jex system of electric propulsion is described in an English electrical paper as a system in which the overhead wires run transversely across the street at intervals equal to about the length of a car; above the middle of the track the wires are cut and joined with an insulator, all the wires at one side being positive and those on the other negative; there are two contact devices on the car, one for each polarity, and they are of sufficient length to touch one wire before leaving the other; by this means no ground return is required. In another issue of the same paper a modification of this system is described in which an insulated conductor is surrounded by a conducting tube in insulated sections with means for connecting these sections with the conductor operated by a magnetic device carried by the car; neither of the methods has yet been used in practice.

WHAT will prove a most useful industrial development is the application of electricity to the cleansing and preservation of boilers. The method employed is the sending of currents periodically through the shell of the boiler. By this means, it is stated, the scale formed on the shell and tube is disintegrated and easily removed.

ELECTRICAL BICYCLES are the latest. The weight of the batteries when filled with liquid is to be forty-four pounds, and the whole weight of the machine is to be 155 pounds.

THERE is in New York one electric lighting company that supplies electricity to more incandescent lamps than there are in all London.

ELECTRIC LIGHTS will make it possible to navigate the entire 35½ miles of the new Manchester ship canal by night as well as by day.

THE city statistician of Chicago reports that there are 150 establishments for "electric lights, works and materials" in that city.

THE underground electrical conduits of New York City have a length of 1667 miles.

THE work of draining the valley of Mexico, which has been in progress of development for nearly three hundred years, will soon be completed. It has cost about ten millions of dollars and some 200,000 human lives. The canal and six-mile tunnel through the mountain range have a total length of nearly forty miles. Nine-tenths of the tunnel is finished and only some 15 per cent of the canal remains to be completed.

Practical Information.

Timepieces Measuring Centuries.

Some animated and interesting conflicts of opinion have occurred between geologists in trying to ascertain how long it took the Niagara river to cut out the "gorge," which extends for six miles below the falls. One of the most modest estimates puts the time required at 6000 or 7000 years; others greatly exceed this. Such a calculation is important, chiefly for the light thus thrown on the interval which has elapsed since the glacial period; for it is admitted that the work has all been done since the retirement from that vicinity of the great ice-sheet which once forced its way down to the Ohio valley from the Arctic regions. However widely the figures regarding Niagara may differ, there is also an apparent disagreement between this and another chronometer of the same kind up in Labrador. The Grand river canyon has a length of twenty-five miles, or about four times that of the Niagara gorge. It is narrower and deeper than the chasm spanned by the suspension bridge; and so is the stream. But the rock to be eroded in Labrador is gneiss, much harder than the limestone crust and the supporting shale at Niagara. Looked at superficially, therefore, it would seem as if ten or fifteen times as many centuries were required to excavate the one as the other. And as the glacial period terminated much sooner down in the latitude of Niagara than it did up in Grand river canyon, 500 or 600 miles farther north, one is puzzled to know how it was done. However, the problem is not the less fascinating for being so complex. The comparison is worth making.

A Note About Water.

Where does all the water in the sea come from? is a question that many a small boy has asked his father, and which many a father has found himself utterly unable to answer. Some idea of where it comes from may be gathered from a glance at the following table of the hourly quantity of water discharged into the sea annually by some of the best known rivers of the world:

River—	Million Feet per Hour.
Amazon.....	3,700
La Plata.....	3,100
Mississippi.....	2,070
Volga.....	1,120
Yukon.....	1,100
Columbia.....	1,000
Danube.....	960
Ganges.....	700
Nile.....	560

This, of course, throws the question back a step. The question becomes, where does the water in the rivers come from? When that is answered by the statement that it comes from the hills, we have gone about as far as we can go. Water is an element, and what its original source may be, no man knows.

The Source of Aluminum.

It is true that every brick in a house and every bank of clay contains a considerable quantity of that beautiful metal, aluminum. In commenting on this subject, a scientific writer says that science has not yet discovered any commercial way of extracting the metal from clay, because in the form it there exists, namely, aluminum oxide, it is combined with silicon oxide, and these two substances behave like a pair of Siamese twins; they are so strongly bound together it is next to impossible to separate them. Therefore, in the production of aluminum, chemists do not use clay, but turn to some material which contains the oxide of alumina free from silica. The best material is a mineral known as cryolite, which comes chiefly from Greenland. It is a double fluoride of aluminum and sodium and an artificially prepared sesquioxide of alumina. These are suspended in a bath of molten chlorides of the alkaline earths, and then subjected to electrolysis by powerful dy-

namous. The sodium salts are decomposed, the metallic sodium seizes eagerly upon the oxygen that was in combination with the aluminum, and as a result the white metal aluminum is freed and settles to the bottom.

Spiders Eat Their Mothers.

One of the most unnatural things in nature, if the expression is allowable, says London *Nature*, is the manner in which the young of the common wolf spider, found everywhere in this country, treat their mother. After the little creature has laid her eggs, she envelops them in a silken covering, so as to make a ball about the size of a pea, and this she carries about with her wherever she goes, and will defend it with her life. When the young are hatched they climb on her back, giving her a monstrous appearance, and ride about until nearly half grown, and as soon as they discover their strength they fall to and devour their mother. As a rule, the maternal relation is recognized in the animal and insect world only as long as the necessity for protection exists; but instances of the young actually devouring a parent by main force and common consent are extremely rare.

THE longest ocean cable in the world is that of the Eastern Telegraph Company, whose system extends from England to India and measures 21,000 miles, says Kate Field's *Washington*. Africa is now completely encircled by submarine cables, which make up altogether a length of 17,000 miles. There are eleven cables across the North Atlantic, though not all of them are at present in use. Five companies control the lines of telegraphic communication between this country and Europe.

SENATOR COCKEREL'S bill to promote aerial navigation authorizes the appropriation of \$100,000 for payment to any inventor from any part of the world who shall, at any time prior to the first of January, 1900, construct a vessel that will demonstrate the safety of navigating the air at a speed of thirty miles an hour, and capable of carrying passengers and freight to the extent of five tons.

THE largest dammed body of water in the world will be secured by the building of a dam at Cloquet, Minn., on the St. Louis river, 900 feet long and 80 feet high, by which back water will be extended 60 miles.

Visit of Debris Commissioners.

On Sunday Col. Benyard and Major Heuer, members of the California Debris Commission, arrived in Quincy via La Porte, where they had been examining mines which had applied for license. They proceeded to Spanish Ranch, observed the operation of the Gopher Hill mine, went down to Indian Hill to examine the Eyraud mine and returned to Quincy Monday evening. On Tuesday they went eastward, stopping at Trayner's and Tefft's, and examining the restraining works on Little Long Valley creek and on Coggs well ravine, then proceeded to Johnsonville. An inspection of the dam on Squirrel creek developed the fact that it was full of tailings, and the mines on that stream were stopped by the Commissioners. Work will not be resumed on Squirrel Creek until a satisfactory dam is built to hold the debris coming down that stream. After examining Vanzini's mine in Yankee ravine, near Jamison City, the Commissioners left on the Reno stage for San Francisco on Wednesday morning, well pleased with their trip through Plumas.

From these gentlemen we learned that numerous mines had applied for license and were operating under the Caminetti bill. The Commissioners expect a largely increased output of gold in the State as a result of this revival of mining by the hydraulic process.—Plumas National Bulletin, June 23d.

BOOKS ON ASSAYING.

BY C. H. AARON.

Part I.—Gold and Silver Ores.**SECOND EDITION—PRICE \$1.**

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt,
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing the
Charge; Mixing and Churning; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible; Assays; Examples of Dressing; The Melting in
Crucibles; Scouring; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ores Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Cupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth, 1893. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.**Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.****SECOND EDITION—PRICE \$1.75.**

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion,
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assay Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhard's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and
Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new,
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition and
the) Extraction of their Respective Metals without
Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore
without quicksilver is liberally illustrated and crammed
with facts. It gives short and concise descriptions of
various processes an apparatus employed in this country
and in Europe, and the why and wherefore. It contains 156
pages, embracing illustrations of furnaces, supplements
and working apparatus. It is a work of great merit, by
an author whose reputation is unsurpassed in his specialty.
PRICE, 33, coin, postage free. Sold by DEWEY PUB-
LISHING CO., Publishers, 220 Market St., San Francisco.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most
complete hand-book on the subject extant; 164 pages
octavo. Illustrated by 12 lithographic engravings and
four wood cuts. Fully indexed. Plainly written for
practical men. In cloth, \$3. Sold by DEWEY PUBLISH-
ING CO., 220 Market St., San Francisco.

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....\$350 EACH,
Including Four-Foot Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ore. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 34 per cent; from East ledge, * * * a saving of 32 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,

E. L. BALLOU, Propr. Ballou Reduction Works.

Extracting Gold and Silver by the Wet Processes.

The following is from the Sydney Telegraph of May 11, 1894:

At the monthly meeting of the Engineering Association of New South Wales, held at the rooms, 70 Pitt street, last evening, Dr. John Storer read a paper on "Some Improvements in Treating Minerals for the Wet Extraction of Gold and Silver."

Dr. Storer pointed out that little had been done in Australia in connection with the wet extraction of gold and silver. An exception was the Mount Morgan gold mine, where chlorination was extensively used to dissolve the gold from the ore. This was due to a variety of causes, one of the main reasons being the long time that had hitherto been required to complete the circle of operations, a time sufficiently long to necessitate the employment of much plant, besides other inconveniences. These methods departed entirely from the use of quicksilver amalgamation, and were based upon the action of one or more of chemical reagents dissolving the metals. The watery solution thus obtained was filtered off from the ore originally containing these metals. When that point was successfully attained the ultimate recovery of the gold or silver was a very easy task. Chief among the difficulties was the slow speed at which filtration of the solutions from the ore took place after the gold and silver had been got into solution. This drawback was common to all methods. In some instances this difficulty of filtration was so pronounced as to entirely prevent profitable work being done. And, in short, the mechanical part of the work stood most in need of improvement, and not the chemistry of the operations. Various endeavors had been made to hasten the process of filtration by artificial pressure. Filter presses had been used, hydraulic pumps employed, compressed air had been taken, and suction applied to the bottom of the filter beds tried, but only with qualified benefit. In all these endeavors, from the corrosive nature of the chemicals employed, the forms of apparatus having movable parts had had too short lives to be a continual working success, and practically filtration under natural atmospheric pressure had been compulsorily reverted to with all its great drawbacks of slowness and uncertainty. The speaker had, in conjunction with Mr. T. B. Lacy, of the Parke & Lacy

Company, devised what was considered an important simplification of the mechanical process of pressure filtration. The apparatus was simple in the extreme. It had no movable working parts, required neither engine nor pumping gear, and working in quantity acquired a speed of filtration greatly surpassing anything hitherto employed. A working size plant had been built, and was then in successful operation in Sydney. It treated for filtering two-ton ore charges at a time. The guiding idea in the apparatus was the direct use of steam, as the source of the pressure or power. By means of specially designed parts the steam direct from the boiler was admitted upon the body of the solution required to be filtered without breaking the surface of the latter. As a consequence of the quick and uniform action of the steam upon the surface of the solution, or water when that was used for washing purposes, only the expenditure of steam on the surface was required to produce the pressure. The machine was divided into two main portions—the pressure tank and the filtering or leaching vat. Dr. Storer then proceeded to give an elaborate and interesting technical description of the machine. The steam when admitted pressed evenly upon the liquid without breaking the surface, and forced it through a connecting pipe into the filtering vat. This vat had a total length of six feet six inches, with a diameter of four feet, and the charge, after being exhausted, could be emptied out at once for a fresh charge, both of which operations were done in less than half an hour. In detailing some interesting and satisfactory results which had been achieved with the machine, Dr. Storer said that experience had shown that different types of ore could be filtered at different rates of speed. The average quantity of solution required to the ton of ore, when using chlorine or cyanide of potassium as a solvent, was 120 gallons, and for the washing, a quantity of water equal to about 50 gallons. There was thus a total of 170 gallons to force through every ton of ore. In a special trial with quartz tailings, 600 gallons were forced through in 50 minutes; while under atmospheric pressure the speed of filtration was 15 gallons in the same time. That was equal to a speed of 40 times quicker filtration by means of the pressure system under notice; or, in other words, with a working filtering plant of equal size, they could filter in a week what would take a working year to do by the prevailing method. With regard

to the cost of the method, the expenditure of steam was equal to about half a horse power engine. The speaker concluded by drawing attention to the importance of the subject, and reading some extracts from American papers which went into the matter.

A vote of thanks was carried to Dr. Storer, who invited the members of the association to inspect the machine at Parke & Lacy's establishment at Pyrmoot. The invitation was accepted for Saturday week.

An Evident Coincidence.

TO THE EDITOR:—In your issue of the 9th Messrs. Almarin B. Paul and G. F. Deetken express perplexity as to the meaning of my statement that in a well-managed Gilpin county (Colorado) mill as much retort gold is obtained by amalgamation as is indicated by the previous fire-assay of the ore, and that the mill bullion being 760 to 780 fine the extraction is close to 76 or 78 per cent.

The explanation, which I ought perhaps to have made more obvious, is as follows: The average extraction at the mill is 76 to 78 per cent. The retort gold is worth about \$16 per oz., equivalent to a fineness of 750 to 780 per thousand. It is a coincidence (and nothing more) that the figure representing the average extraction should be nearly the same as that representing the fineness of the mill gold. Thus, if 20 tons are found on sampling and fire assay to contain 1/2 oz. per ton, or 10 ozs. altogether, the mill will yield 10 ozs. of retort gold. The ore contains 10 ozs. of fine gold, worth \$20.67 per oz., and the mill extracts 10 ozs. of bullion, worth \$16.10 per oz. Out of a value of \$206.70 there is extracted \$161, equal to a yield of nearly 78 per cent. The mill gold is 780 fine. The coincidence is evident.

I regret that it was not, owing to the absence on my part of fuller explanation, so obvious to Mr. Paul, whose references to his age and experience were uncalled for and unnecessary. No one is too old or too young to learn. I yield to none in my respect for the pioneers of the milling practice of the Great West, but in no field of inquiry has the young man so much to learn and the old one so much to unlearn. Yours faithfully,

Deper, Col., June 23, '94.

Assessment Notices.

OCCIDENTAL CON. MINING COMPANY—LOCA-
tion of principal place of business, San Francisco
California; location of works, Silver Star Mining District,
Storey County, Nevada.

Notice is hereby given that at a meeting of the Board
of Trustees, held on the thirty-first day of May, 1894,
an assessment (No. 18) of Ten Cents per share was
levied upon the capital stock of the corporation, payable
immediately in United States gold coin to the Secretary,
at the office of the Company, Room 69, Nevada Block,
No. 309 Montgomery Street, San Francisco, California.

Any stock upon which this assessment shall remain
unpaid on the fifth day of July, 1894, will be delinquent,
and advertised for sale at public auction; and unless
payment is made before, will be sold on TUESDAY, the
thirty-first day of July, 1894, to pay for the delinquent
assessment, together with the costs of advertising and ex-
penses of sale. By order of the Board of Trustees.

ALFRED K. DUBROW, Secretary.
Office—Room 69, Nevada Block, No. 309 Montgomery
Street, San Francisco, California.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Mill-
men, Hydraulicians, Mining Engi-
neers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hy-
draulicians of the country. It abounds with useful
tables for ready reference, in which the results of ab-
struse calculations are all placed in a form so that one
can find what he wants in a moment. For the engineer
the principles, formulae, coefficients, etc., are given; and
for those not familiar with higher mathematics, ex-
ample, rules, and tables are prepared. Thus the needs
of the scientist and the practical miner or millman are
each met. It is the most complete work on the subject
yet published, and is especially applicable to the Pacific
Coast.

Table of Contents.

The following brief abstract of the contents will give
an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics;
Rules Deduced from Formulas Obtained; Examples
and Calculations; Extensive Tables for Ready Refer-
ence; Fundamental Laws of Hydraulics Demonstrated
and Expressed in Formulas and Rules; Flow of Water
through Openings; Weir Coefficients; Triangular
Weirs; Flow of Water Over Quadrant Weir (tabulated);
Application of Tables; Submerged Orifices; Flow
Through Orifices in Thin Partitions; Tables and Appli-
cations; Miners' Inches; Tables and Calculations; Flow
of Water Through Short Tubes and Compound Tubes;
Flow of Water Through Pipes; Tables of Velocities and
Cubic Feet Flows for Given Fall per Mile and Diameter
of Pipe; Coefficient for Bend-Circular and Angular;
Flow Through Nozzles; Inverted Siphons; Flow of
Water in Open Channels; Extensive Tables; Rough and
Ready Notes; Hints for Speedy and Approximate Esti-
mates, etc.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE BAY STATE MINE.—*Ledger:* The Bay State mine is one of the old properties of the State upon which a hoist was erected and a shaft sunk about 40 years ago. Three years ago the people of Plymouth, who have always hoped for great things from a proper, thorough and systematic prospect of the lode which was through their town end to the Cosumnes river, organized the Bay State Mining and Development Company, and have put a great many thousands of dollars into the proposition of deep mining in the country between Plymouth and the river. During the progress of the work the company has encountered several setbacks, the chief among them being the water encountered in the drift at the 300-foot level, which has thrown them back at least twelve months in their work. At 80 feet the ledge was cross-cut and the rock sampled, a test being made which showed the amount of gold contained therein to be \$1.62 per ton. That it is true was not very encouraging to the stockholders, but work was pushed on down and at the 300-foot level they found a "horse" had come in the formation, so they had to drift some distance north and south to again strike the ledge. The ledge here widened out and a milling test was made upon a number of tons with the result that \$7.78 per ton was obtained. The increase from \$1.62 to \$7.78 per ton in 220 feet of depth was so encouraging that the drifts at the 300, where the bothersome water was encountered, was bulkheaded and the work of sinking continued without crosscuts until the 500 level was reached. When the shaft was down to the 500 level, crosscutting to the ledge was pushed forward at the 400 and 500 stations with the result that the ledge was encountered this week but a few feet from where Mr. Jones calculated to find it.

El Dorado.

Republican: E. Bind of this city is superintending some work in deep gravel at Pleasant valley in the interests of the San Francisco Bridge Company. A shaft is being sunk through the lava. Work was commenced in an old shaft about 50 feet deep, which has been excavated to the depth of 126 feet through the lava without finding bedrock yet. It is believed that this deep ground is the continuation of the gravel channel partially opened through a shaft many years ago by Fleming & Sons. On John Fink's place, paying gravel has been discovered and the channel is supposed to be a tributary of the deeper ground that is being prospected by Bind. Snow Bros. have been working in some very rich gravel on the Newtown side of the lava ridge and this also lends encouragement to the idea that the deep channel will contain paying deposits.

The five-stamp mill recently started at the Gignac mine at Texas Hill near Placerville was cleaned up a few days ago after a run of 300 carloads. The owners report the result as highly satisfactory and say they intend to increase the mill to ten stamps as soon as possible. They have been breasting about four feet of gravel on the bedrock tapped by means of a tunnel.

Inyo.

THE NEW DIGGINGS.—*Independent:* Early in the week we made a visit to the newly-discovered placer diggings in Mzourka canyon. The scene of the discovery is in the region of the "Hickey Hood" spring, about six miles from Citrus. There are quite a number of Mexicans there who were engaged in cutting and packing wood. While looking for a spring that would be nearer his camp a Mexican named Gomez found gold in the canyon next north of the Hood Spring canyon. He had led comrades to prospecting, and they have found gold the entire length of the canyon, a distance of over a mile. The discovery caused many others to visit the locality, about 50 men being camped at the spring last Saturday night. "Colors" have been found in several of the adjacent canyons, but not in sufficient quantities to pay. The "Mexican gulch," as it is called, is the only place where gold has been found in paying quantities. On Saturday we saw about 350 pounds of dirt taken from this gulch and panned, and it yielded over three dollars. The dirt was not selected, but taken from the bottom of the gulch and about a foot from the surface. The formation of the range of hills through which the canyon runs is argillite, and the pay dirt is light gray in color and is formed from the elate by corrosion. Underneath the argillite is limestone, and underlying all is granite, which forms the summit of the main range. There has been a great deal of prospecting for quartz in the locality for over 30 years, but no paying ledge has ever been found. As the placer gold is not found in gravel, but in the crumbled elate, the supposition is reasonable that it was deposited where it now lies during some mighty eruption in past ages. The country is highly volcanic, and this seems the most reasonable conjecture as to the source from which the gold came. There are about 15 Mexicans at work and they are all making wages, although they are operating in the most primitive manner, packing the dirt to water and washing it in gold-pans. Bob Curasco has a good claim and he intends putting in a dry washer. By this means the ground can be worked much more rapidly. There is also plenty of water to run several rockers, and this system will probably be tried. Some further developments may be made in the near future.

Nevada.

Grass Valley Union: The mill at the German mine, Washington, has been started up. Superintendent Goss has everything in good shape

now and will work the mine to its fullest capacity. The sawmill at the Oak tree is running full blast getting out money for the new mill and other buildings at the mine. The Oak Tree is grading for a new mill about twice as large as the present one, and additional concentrators and other new machinery will be put in and the plant enlarged. Superintendent Garland of the Rainbow is also preparing to put up a mill. The mine has none at present. The Rainbow is turning out well and a mill is a necessity.

Placer.

AROUND DUTCH FLAT.—*Colfax Sentinel:* At the Alta mine, in which J. E. Doolittle and several other capitalists are interested, the tunnel is now in 1100 feet, and it will be several months before the channel will be tapped. The channel that the tunnel is being driven to tap is the white channel formerly worked through the Alta shaft. Already some good prospecting blue gravel has been struck that will pay wages, but the tunnel is being driven ahead to reach the white channel as soon as possible. The mine is being worked by the same parties who are improving Lake Alta.

At the Gold Shaft, the new shaft at Dutch Flat, the gravel continues to prospect well. Last week a waterwheel was put in to boost the gravel and pump the water from the mine.

At the Polar Star mine at Dutch Flat last week, a nice little prospect was picked up in the prospect tunnel that is being run. No extensive body of gravel has yet been discovered, although some of the richest drifting ground in early times was right adjoining where this mine is.

Some very good ground has been struck again in the Paragon mine at Bath, and the company has canceled the lease made a short time ago and is again working the mine.

San Diego.

Union: The old Cerro Muchacho is still pounding away night and day, not turning out quite as much gold as in the past, but still working away and doing well, paying nice monthly dividends. The Gold Rock forty-stamp mill gets away with 100 tons of ten-dollar rock per day without any trouble. The great vein on the Queen mine is now down over 300 feet, with pay ore more than 100 feet wide. At Picacho the great pumping plant at present stands idle. Efforts are being made by those who have the American control of the property, to put the rich mines to producing. J. M. Mendeive, agent for Dr. D. W. C. Jayne of New York, has sold the old Picacho group of gold-quartz mines, comprising the St. George, Gosben, Venus and Mars, with the fifteen-stamp mill, to Colonel D. K. Allen, representing a wealthy Chicago syndicate, who will start up the mill at once, adding fifteen more stamps now, to be followed by twenty stamps more as soon as they can be erected, making fifty stamps all told. Wood is abundant and cheap along the river, and the Colorado furnishes a never-failing supply of water.

NEVADA.

Ferguson District.

Helene Lode: The DeLamar Company has commenced work on a new tunnel about 300 feet south of the Jim Crow. This is to be used as the main tunnel for working their group of mines.

The DeLamar Gold Mining Company has en route from Milford one of the latest improved artesian boring machines. Four men, direct from the factory, are in charge of the machine, which is expected to arrive next week, when the work of determining the water question of the district will be begun. The machinery is guaranteed to be first class in every particular, and has a capacity of boring 3000 feet.

Three men have been working on Rig's Springs the past month and have succeeded in developing three inches of water. This proved satisfactory to the owners and they suspended further operations for the present. These springs are situated eight miles south of Ferguson district and the water could be piped to the DeLamar mines with the assistance of one pump at the springs.

J. R. DeLamar arrived by private conveyance last Monday, coming from Desert. He gave the mine a careful inspection and was well pleased with the improvements since his last visit. The Captain spent several days looking at springs and water sites, and stated that as soon as the water question was definitely settled a reduction works would be erected somewhere near the mines.

ARIZONA.

THE JAYNE CLAIMS SOLD.—*Yuma Times:* The Jayne claims at Picacho, consisting of the Gosben, Marsh, Venus and St. George, have been sold to Geo. M. Snider of Chicago, who has also purchased the mill at the river. The claims are all patented and are about four miles from the river. They have been extensively worked in past years, the rock running from \$3 to \$40 gold a ton. There are two shafts on the Venus 200 feet deep, connected by a tunnel 400 feet long. On the Marsh is a 450-foot tunnel. The Gosben has an incline 200 feet long, a tunnel 220 feet, shaft 220 feet, and a short tunnel 60 feet. The ore was formerly hauled by teams to the mill, but it is said the new owner will build a double track cable tramway. The mill is 15 stamps, and will be increased to 30 or 40 and new boilers put in. The price paid for the property is said to be \$125,000.

MINING NOTES FROM THE HASSAYAMPA.—*Helms & McLeish* are preparing to work the tailings at the old Wickenburg mill by the cyanide process. Mr. Hunt is chemist. The ore from which these are the tailings was hauled from Vulture and worked at this mill years ago, in the palmy days of this old town. There is a big pile of tailings and they are supposed to be rich enough to give big returns. A number of men are at work.

There are about 100 men at work at the San

Domingo placers. There are two stores, a saloon, milkman, etc. Considerable gold is taken out of these placers by the dry washer process, and it is said to be a fine quality. These miners at San Domingo are mostly "children of manyana."

BRITISH COLUMBIA.

WEEK IN CARIBOO.—*Kamloops Sentinel:* A. Wells, who has been on a trip through Southern Cariboo, returning to Kamloops last week, reports work being carried on vigorously on the Horsey and Cariboo companies' properties. A fortnight ago 175 men had gone into the Horsey mine, but some had come out the previous week, leaving the number working about the same as before. The excavation of the ditch is being done by sub-contracts. Water has been high, but not so bad as to interfere with work to any great extent. On the Cariboo property about 200 men are working. Water will be brought from the south fork of the Quesnelle to what is known as the China claim, a distance of about a mile, and it is expected that hydraulicicking will begin within two months.

SAVONA CINNABAR MINE.—*Col. Christopher* has completed development work on the cinnabar claim near Savona, and is now awaiting the arrival of an expert who will direct the building of the retorts for purifying. This plant is of comparatively low cost and will be erected at the mine. Wood will be the fuel and that can be obtained very conveniently. Col. Christopher is well satisfied with the prospect of the mine, which promises to yield highly profitable returns. Cinnabar running 2 per cent in mercury has been worked profitably, but the claim at Savona in the true vein runs from 50 to 60 per cent, so that it appears that the owners are fully justified in placing a high value on their property. In fact, Col. Christopher considers the ore the richest he has ever seen. The property is not for sale, so that there would be no object in booming the mine. Prospecting has shown that there is no danger of the vein pinching out, and it may safely be predicted that this claim will be one mining property which will add to British Columbia's fame as a mining country.

ENCOURAGING RESULTS.—*The Kootenay Hydraulic Mining Company* at Fort Sheppard recently completed a most important cleaning-up. Their operations have been directed to ascertain precisely the value of their property on the north bank of the Pend d'Oreille river. To this end they collected all the water from the Seven Mile and Nine Mile creeks and directed it into their main ditch with a head of 250 feet above the monitors at the level of the Pend d'Oreille river. They sent through their sluices 2200 yards of gravel, and the weight of the quicksilver amalgam shows a yield of \$525 in gold, equal to nearly 24 cents per cubic yard, some of the nuggets being of a good size, the largest being worth \$5.85.

COLORADO.

NEAR SAN JUAN.—*Silverton Miner:* The Occidental and two other claims, Cement creek, owned by Robert Hook, have been opened up to the extent of about 400 feet of work. The Occidental is in a large body of low grade ore, containing more gold than silver. The vein is fully 30 feet wide. A Philadelphia and New York company will erect a stamp mill on the property, the first \$500 payment having been made. The larger proportion of the ore carries 12 per cent copper and is well adapted to the new process.

The M. D. mine, Eureka gulch, C. E. Felver manager, is developed to the extent of about 200 feet of tunneling. The vein is 25 feet wide and is considered the mother vein of the Sonny-side country. Several mill runs have been made on M. D. ore from different strata of the vein. From the lead stratum 60 per cent lead, 1 ounce gold and 13 ounces of silver were obtained, and from the honey-combed quartz stratum, which is not much thicker than the average Silverton hotel bed blanket, a mill run was had of a trifle over 50 ounces gold.

THE COCHITI DISTRICT.—*Warner A. Root*, of the Denver Mining Record, says the Cochiti district, which extends several miles in length by three to four in width, is about 40 miles in a westerly direction from Santa Fe, and reached by a good wagon road all the way from that city. The nearest railroad point, however, is Welleco, on the Santa Fe, from which point stage lines run daily, a distance of about 24 miles.

"The principal mines so far developed, which is not saying much," says Mr. Root, "are the Washington, Lone Star, Iron King and Crown Point. The general character of the country rock is bird's-eye porphyry overlaid greatly with trachyte lava rock. The discovery point in most of the claims is where the outcroppings appear to be high blowouts or chimneys, and so far these are from 10 to 50 feet in width. The vein rock is more or less heavily mineralized quartz, with black sulphurets of silver, carrying gold, and the richer the ore is in silver the more gold is found."

"So far as I visited, there seems to be three distinct veins, varying in width, extending through the high ridges from Pino canyon southward through Colla, Peralto, La Jara and onward even into Bear canyon; and by development the ore is said to be nearer free milling from Colla canyon to the south. While Eagle or Bland City is growing rapidly, it is generally conceded that Allerton will be the principal camp or town of the district, lying as it does near the mouth of Pino canyon. From here wagon roads to Madia Dios and Cochiti anyone on the north, Colla, Peralto and La Jara canyons on the south, can be built. Forests of heavy pine and cedar timber abound on all sides."

"It is at Allerton, where General R. W. Woodbury and J. W. Bailey, a mill man of many years' experience in the Rocky moun-

taine, and who are the principal officers of the Cochiti Mining and Milling Company, are erecting an amalgamating mill of 30 tons capacity. The process of treating the ore will be by cylinder roasters, running through crushers and Cornish rollers and over amalgamated plates. Mr. Bailey is of the opinion that this process will save 90 per cent of the gold and silver in the ore. The product, run into bars, will then be shipped to the Denver mint. The Iron King mine, situated near the Lone Star and Crown Point mines, about eight miles away above Eagle or Bland City, and owned by this company, is by good judges considered the richest gold and silver bearing ledge in the district, and from the present outlook 50 to 60 tons can easily be shipped daily for years to come, although it may require some development to prove this. Should the mill prove a success in the treatment of the ores of the district, then others will be erected and the output of bullion product be most wonderful."

"It is expected sufficient water can be taken from springs in Pino canyon, some three miles above Allerton, but should such be not the case, it will be brought across the divide between Cochiti and Pinone, probably a distance of five miles, and with a fall of 50 feet in the last mile or so."

"A great many Colorado miners and prospectors are in the district, and representatives of much Colorado capital are making thorough investigations as to what is there and the future possibilities of the district."

LIKE A FAIRY STORY.—*There arrived in Denver last Wednesday over the Denver & Rio Grande from Aspen a car of nearly pure silver ore from the Smuggler mine, and the single car of ore is worth just \$400,000.* The car was under guard at Aspen all night, and when it goes through it will have just a few guns on the inside.

According to the newspaper story, the car contains the purest lot of silver ore ever shipped out of a mining camp, which lies about the car in pieces weighing from an ounce to 1800 pounds. This pocket of ore was struck in the Smuggler mine about six weeks ago, and has been kept under guard ever since. Its great value may be realized when it is remembered that at the present prices of silver it will bring \$400,000.

SMELTING PROCESSES IN THE SAN JUAN.—*Durango Southwest:* Four years ago but one smelter was in operation in the San Juan mining district. The ores to supply it and keep it running steadily came from Silverton, Red Mountain and Rico. The entire product melted was less than 20,000 tons. To-day we have in operation the San Juan smelter and the Standard smelter at Durango, the Grand View at Rico, the Loder at Ouray, the Crooke smelter now in operation and the Walsh smelter ready to blow in at Silverton, and a small plant at Lake City, seven in number; and still there are those who see no improvement in mining or smelting in the San Juan country. As against a smelting capacity of 100 tons a day four years ago, we have now a capacity of over 400 tons; and while we are importing ores from other districts to keep the smelters going, an equal amount of ore not mined in the San Juan is going to outside points. Some curious phases present themselves in connection with ore shipment and smelting just now. Ores from Ouray, Telluride, Rico and Ophir reach Durango. Ore from Red Mountain passes the Silverton and Durango smelters to go to Rico. Ores from Leadville and Eagle river pass the Leadville smelter and reach Durango. Ore from Silverton and Red Mountain and Rico pass through Durango and go to Pueblo. The mine-owners certainly have a choice of markets and the smelters are all on the qui vive for the product of the different mines. It is safe to say, with silver at 65 and 70 cents, a larger smelting product from the mines of the San Juan district will be taken out of the San Juan mines during the next six months than was ever before known.

MONTANA.

GENERAL NOTES.—*Inter-Mountain:* The week at the mines has been uneventful. The Boston & Montana is working as usual, except that operations have been curtailed at the Alex Scott. The ore shipments to Great Falls continue regularly. The Anaconda has been hampered during the week by washouts at the works near Carroll, and this has cut off the supply of ore cars. In consequence the mine has been running lightly during the week, but all is smooth sailing again. The Butte & Boston, Parrot, Colorado and Butte Reduction Companies have nothing new to report. The Lexington mill is again in operation.

At the Heinze works several important and extensive changes are in progress, in consequence of which the Glegarry mine is not producing ore. Mr. Heinze has decided to do away with ore hauling by teams, and when the present changes are made the ore and concentrates will all be handled by rail. Ore bins are being built at the Glegarry and the concentrator. The Montana Union track, at a point near the concentrator, will be elevated, so that it will be about 30 feet above ground at the concentrator. The ore from the Glegarry will be dumped at the concentrator and then moved by rail to the smelter; thence the matte will be shipped via the Montana Central. A saving of 50 per cent in ore-hauling charges will be effected by this change.

At the Clipper mine, Camp Creek, drifting is in progress.

At the Evelyn mine ore shipments are being regularly made.

Quite an excitement was caused during the week by a rich strike of ore in the La Monte mine, which lies west of the Evelyn. It is understood a shipment of ore went \$280 to

the ton in silver and about \$60 in gold. The La Monta is owned by Thomas Gorrie, and is being worked under lease.

Two new boilers are being placed in position at the smelter, and in the future the power to operate the concentrator will be conveyed from the smelter plant.

The Poorman mine is again in operation, turning out 60 tons of concentrates per day.

UTAH.

Beaver Co. Utahian: Messrs. Nelson and Lambert, who returned from the Gold Mountain mining district, report favorably. New machinery is being put up and the yards cleared for a long run at the Sevier. Eighteen men are at work there, and a great many more are in that district working placer claims. Some new machinery is being put in at the Annie Laurie mine, which is situated north of the Sevier.

Messrs. Nelson and Lambert have returned to prospect for placer claims. There are already eight or ten crowds of men, with from four to ten in a crowd, washing gold from the sands of the little creek. They claim to be making \$1 to \$8 per day.

WASHINGTON.

Tacoma Ledger: Placer mining on the Similkameen has been suspended for the present on account of the spring rise. There promises to be more gold taken out of the swift river this year than for 30 years past. Prospectors on the Columbia river are anticipating a big find in some of the banks and bars that are now being washed by the unusual high stage of water. And after the water recedes to the natural level many a placer miner expects to make a stake. The Columbia Placer Mining Company is engaged in the work of separating flour gold from the river sand near the mouth of the Yakima river. It has met with gratifying success, though it is now shut down for a time on account of high water in the Columbia.

Coast Industrial Notes.

—Three vessels now loading at this port will carry over 3,000,000 feet of redwood lumber to London.

—On the 1st inst. there remained 12,743,000 bushels of wheat in California, against 7,466,000 on June 1.

—A million and a half in bonds has been issued by the Oregon Railway and Navigation Company to repair the flood damage.

—The control of the Starr mills at Vallejo and Wheatport has been secured by the flour mill combine. Starr & Co. are to get \$2000 a month.

—The Parke & Lacy Company have sued eleven insurance companies for \$42,500 due them on a loss on their lumber mill, burned at Snoqualmie, Wash., last December.

—Articles of incorporation of the Seattle & Lake Washington Waterway Company, with a capital of \$3,000,000, have been filed by a company, which proposes to connect Elliott bay with Lake Washington by a canal.

—The survey of the Alaska boundary is being carried on by the Canadian surveyors principally by the new photographic method. Canada has appropriated \$250,000 for this survey and the United States \$60,000.

—The California Canneries Company has been incorporated with a capital stock of \$500,000, of which \$300,000 has been subscribed. The object of the company is to centralize and control the fruit-packing establishments of the coast.

—Fishermen at the mouth of the Columbia report that unless there is a good breeze they cannot do much, the high water having made such a swift current that they keep away from the regular fishing grounds out of fear of being carried to sea.

—Frank Cardin and J. T. Bibb, composing the Tacoma Grain Company, have bought of the receiver of the Northern Pacific Elevator Company the thirty-nine grain elevators belonging to the Northern Pacific system in the Northwest.

—The steamer Boscowitz, from the north, brings word of the loss of a party of seven Indians in attempting to run the high water now filling the Skeena river canyon. She also brought back Prof. King, Canadian boundary commissioner, who, having placed parties in the field, came down for the summer.

—A mammoth fir tree was recently felled at the camp of Captain R. E. Myers in Birch bay, near Whatcom, Wash. Three cuts from the tree scaled as follows: The butt log, 24 feet, scaled 8120; second cut, 24 feet, scaled 6800 feet; the third cut, 26 feet long, scaled 5232 feet, making a total of 20,222 feet in 74 feet of the tree.

—A contract for building the first forty-six miles of the Monterey & Fresno Railroad has been let for \$782,000. This will build the road to Hollister, whence it will go across the mountains into the San Joaquin valley. The contractor has agreed to build and complete the road by May 1, '95. The projectors of the road have floated \$3,000,000 of bonds in New York.

Market Reports.

The Markets.

SAN FRANCISCO, June 28, 1894.

At the current rate of the week the commercial value of the pure silver in a silver dollar is 48 1/2 cents. The quotations are very low; favorable comment and promised legislation do not aid its appreciation. The statement is made that "the central point around which the present system of gold-metallism revolves is the increase of exports from British India, which are paid for in cheap American silver, and the decrease of exports from the United States which have to be paid for in gold, causing a drain of that metal from Europe, where it is tolerably scarce. A silver dollar (U. S. currency) cannot be obtained in any part of Europe for less than 97 cents, nor will a gold dollar fetch more." If so, vast opportunities open before the enterprising European counterfeiter who, it is reported, are now coining bogus American dollars at a cost of fifty cents each.

New York Prices.

NEW YORK, June 28.—Following are the closing prices for the week:

A London cable says: The improvement in stocks continues. The statement of President Cleveland has had a good effect here. Americans rose steadily to-day and closed at the best. It is believed that the worst of the trade depression in America is over, but only a slow recovery is expected. The other markets partly responded to the improvement in Americans, but business is still insignificant. The Indian Council sold 65 lakhs of rupees ranging up to 13 5/32. The amount to be offered next week will be reduced to 40 lakhs.

New Branch Office.

Fraser & Chalmers have established a new branch office at Denver, Colorado—527 Seventeenth street, opposite the Denver Club, and one square from Brown's Palace Hotel. It will be in charge of Mr. H. K. Ayres, who has been connected with the house at home and abroad for many years, and has had an extensive experience in important problems involving metallurgical and power plant. Visitors in Denver are invited to call at this office and make use of it in matters of correspondence, reference to periodical files, and other conveniences.

Mining Share Market.

SAN FRANCISCO, June 28, 1894.

The general verdict on and off the street is that the main stocks are worth more than current quotations would indicate. It is not unusual to find the stock sales figure a poor indication of the mine value. The general depression and next week's holiday aided in hearing the market. Sanguine operators think the disbursement of July dividends will ease money matters to the extent of increasing active purchases. The swing of the pendulum has now oscillated from Con. Cal. and Va. at \$9 to \$2.50, with the mine looking better when the stock is \$2.50 than it did when it sold at \$9.

Of the mining outlook on the Comstock, Dan De Quille, in the S. L. Tribune, says:

As regards the mining situation on the Comstock, it is at several points much more favorable than it was several months ago. A really large and valuable body of ore is fast being developed at and below the 1650 level of the Consolidated California and Virginia mine. On the 1650 level there is a width of about six feet of solid black sulphure ore assaying well up into the hundreds at some points, and averaging about \$100 a ton. This rich ore still continues at a depth of twenty-eight feet below the 1650 level, where a crosscut shows it to be twelve feet in width. At the 1700 level a crosscut is just entering the ore body, the east side of which it has penetrated some two feet, showing ore that assays \$30 a ton. The indications are that the ore vein will be found to be much wider at this point than in any of the openings above. It is also likely to be found richer than at any point above, as instead of beginning in ore of low-grade material, it starts at once in good paying ore. The ore is being worked at the Morgan mill on the Colorado river, to which several hundred tons have already been shipped.

This little bonanza, which yields a large per cent in gold, is now the principal hope of our people. Had we half a dozen such along the Comstock lode, all would be well with us for many months, as most of our idle miners would then be able to find employment. Promising indications are being found at several points, and almost any day we may hear of something of value being found. I have great hope of a find being made in the exploring drifts that are being run to the westward in the Ophir on the level of the old Central tunnel. In that direction goodly deposits of rich gold-bearing quartz are liable to be found. It will be recalled that the Rowe vein yielded several hundred thousand dollars in gold. It was a feeder of the Ophir, and no doubt there are other feeders not yet found, as in the early days attention was given to nothing but the main bonanza, which was followed to the 500 level, where it pinched out. Parallel veins in the shape of feeders were not looked for, and had they been, would not have been easily found on the surface, as the slope of the mountain is covered to a considerable depth with debris from above.

Other leading mines of the Comstock are yielding more or less ore, and are diligently prospecting in the hope of finding something that will enable them to do better than barely keep alive, as at present. But very little can now be done with mines that are purely silver bearing. There is now more truth than ever before in the old Mexican saying that "it takes a gold mine to work a silver mine."

The Enterprise says: The Consolidated California and Virginia letter which follows, shows that the face of the west crosscut on the 1700 level is in \$30 ore. There can be no gainsaying the fact that a large and rich body of ore is that which has recently been discovered. The facts known show that the body has already been marked out, and that the ore assays from \$30 to \$500 per ton. The opinion of mining men is that the ore extends both above and below the points at which it has been reached, and it is generally thought that the ore above the 1650 level is of greater richness than any taken from the new bonanza. However this may be, enough is known to assure the fact that men will be put to work, and at least a partial revival of the former prosperity of the Comstock will take place.

James K. Lynch, assignee of Robert Sherwood, has sued the Bodie Tunnel and Mining Company to recover \$16,723.86 upon a promissory note dated June 30, 1890, with interest thereon from April 30, 1894.

In the suit of Wetmore against Barrett & Co., stock brokers, the Supreme Court has confirmed its former opinion in the case of Cashman vs. Root, practically deciding that dealings in stocks on a margin are illegal, the judgment in favor of Wetmore for money given to the defendants to buy stock on a margin being affirmed. It is thought that the defendants will take the question up to the Supreme Court of the United States.

In the suit of M. W. Fox vs. The Hale & Norcross, wherein \$1,250,000 is involved, there is a new phase involved, the case having been transferred from Department 2 to the Supreme Court in banc; this is interpreted to mean that Justices McFarland, Fitzgerald and De Haven have not been able to come to an agreement.

William Megginson, of Columbus, Ohio, has brought suit in the United States Court against the Lone Jack Mining Company for a claim in Slug Gulch, El Dorado county, which he says is his property. It is valued at \$10,000.

At the annual meeting of the stockholders of the West Con. Va. & Cal. Mining Company 93,056 shares were represented. The following officers

were elected: M. W. Fox, president; G. P. Thurston, vice-president, and A. D. Carvill, P. J. Lain and R. Collins, directors. P. H. Andros was re-elected secretary, and H. W. Tangerman superintendent. The secretary's financial statement showed a balance of \$9121.80 in the credit side of the ledger.

The following illustrates the changes of the week:

Patents Issued to Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast, 220 Market Street.

FOR THE WEEK ENDING JUNE 19, 1894.

521,491.—OIL-ON FAUCET—G. W. Arper, Oakland, Cal.
521,534.—CARPET FASTENER—P. Coorick, Seattle, Wash.
521,640.—FOLDING CRATE—A. W. Coate, Ukiah, Cal.
521,748.—TOY BANK—J. W. Coate, A. S. Page, S. F.
521,642.—LAMP EXTINGUISHER—O. W. Cottrell, Wash.
521,766.—PIPE—O. S. Hamill, Los Angeles, Cal.
521,541.—ROTARY ENGINE—H. D. Holland, S. F.
521,472.—WINDOW—F. M. Mabney, S. F.
521,767.—TURNS—J. McNamara, Seattle, Wash.
521,663.—ORE GRINDER—N. C. Moore, Newhall, Cal.
521,545.—CAR COUPLING—W. C. Nelson, Santa Rosa, Cal.
521,768.—POWER APPARATUS—A. S. Page, S. F.
521,551.—GAS ENGINE STARTER—J. W. Raymond, S. F.
521,628.—OABINET—Bertha S. Wilkins, Los Angeles, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order. American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LANTERN OR LAMP EXTINGUISHER.—Charles W. Cottrell, Washoul, Wash. No. 521,642. The object of this invention is to provide an extinguisher which is readily attached to lamps or lanterns. It consists of an air tube of a diameter which will allow it to pass through one of the apertures in the foraminous ventilator disk bent laterally at its upper end, and provided at its outer end with an air bulb and an attaching device secured to the tube between the bulb and the bend. The pipe has its inner end open and in proximity to the wick top, so that when the air bulb is compressed a jet of air will be forced through the tube to extinguish the flame.

POWER STORAGE APPARATUS.—Albert G. Page, assignor of one twenty-fourth to Frank H. Johnson, San Francisco, No. 521,768. The object of this invention is to provide an apparatus through which power is transmitted from any suitable source, and by which said power is stored and utilized to increase the effective force which is applied to the driven machinery. It consists of independent vertical shafts standing in line and movable with relation to each other, mechanism through which power is applied to rotate the uppermost of the shafts, a disk secured to the lower end of each of the shafts, and vertical lever rods crossing each other spirally having their ends loosely connected with the disks and horizontally disposed weighted lever arms connected with these spirally disposed rods, so that the weights are raised when the rods are twisted by the rotation of the vertical shaft, but will fall as soon as the speed of this shaft is slackened, and will thereby apply a certain amount of power by reason of the weights, to continue the motion of the shaft.

GEO. E. BELMOR,

OF THE BELMOR BOILER WORKS,
Has Removed from 210 Mission St. to 52, 54 and 56 Bluxome St., bet. 4th and 5th.
(To the old H. W. Rice Machine Works.)
FOR BOILERS, DREDGING BUCKETS AND SHEET IRON WORK, CORRESPOND.
